look promising, for neither the frost nor birds seem to have injured them in the least, and as there has not been any serious frost for several weeks we may now hope to have a full crop of fruit. Morello Cherries on both north and north-east walls have set their fruit wonderfully, being more forward than the early sweet varieties growing in the open orchards. How to account for this peculiar freak I do not know, unless it be that the wood was more perfectly ripened and therefore less injured by the frost, as was the case with Cherries of the early varieties growing against south and south-west walls, the fruit of which is now stoning. It would be interesting to know if fruit trees in other parts of the country have been affected in the same way as they have on the cold, heavy soil in this district. It will also be instructive to watch their progress through the summer till the fruit is ripe.

H. C. P.

**Grape West's St. Peter's.**—One seldom meets with this Grape now-a-days, probably on account of its strong resemblance to the Black Hamburg and the comparative smallness of its bunches. I maintain, however, that where room can be spared this Grape is well worth growing, as, independent of its hardness and good setting qualities, it is of excellent flavour, and, keeping better than the Hamburg, comes in most acceptable between that variety and Lady Downe's. The berries are rather small, but they always colour well, and a heavy crop may always be taken from healthy Vines without fear of any evil results. It is all the better for being treated to a comfortable temperature, but does not require strong heat.—J. CRAWFORD.

**Forcing late Peaches.**—There are, I think, many of the so-called late Peaches, and which, it is true, ripen their fruit late in autumn when treated simply to a cool house or open wall, that would readily respond to a warmer temperature and even force well. I have been told on good authority that Late Admirable Peach will force well, and I have myself proved that both Sea Eagle and Princess of Wales do well if started in January and brought on in heat. I have both these varieties in a span-roofed house, side by side with Stirling Castle and Violette Hative, and they follow these varieties in the order named. Sea Eagle has a remarkable constitution, bears continuously and well, and is, especially when ripened under the above treatment, of excellent flavour. Of course we are not short of first and second early Peaches and Nectarines, their names being legion; nevertheless for those who desire extra large, hand-ome fruit for exhibition tolerably early in the season, Sea Eagle and Princess of Wales are worthy of a place in a house that is to be started during January.—J. N.

#### NOTES FROM HIGH ELMS.

ABOUT two miles from Orpington Station in Kent is High Elms, the residence of Sir John Lubbock, and when there a few days ago we made notes of some of the more interesting features of the gardens.

Of indoor plants the greatest attention is paid to the Carnation, and Mr. Morter, the head gardener, has raised many fine seedlings, in which the Malmaison character is shown, these seedlings resulting from crosses with some of the finest varieties in cultivation. None of them were named, but a few were quite worthy of some distinction, especially a fine buff-coloured kind in the way of Mrs. Reynolds-Hole, a clear, shining, yellow-flowered variety. All the plants were in robust health, especially the bluish and ordinary forms of the Malmaison, no spot or disease of any kind appearing on the leaves. The house of Carnations here was bright with bloom, and we were pleased to see that in the seedlings fragrance was strongly marked. This is not always the case, but the fragrance of the Carnation is far too precious to lose. Primula Sieboldi was very fine, and by hybridisation an excellent race has been obtained with a profusion of large flowers of much deeper colour than usual.

Some houses were filled with Caladiums, Dracenas and Crotons. The Caladiums were chiefly represented by that dwarf race shown at times by Messrs. J. Veitch and Sons, of Chelsea. This is a very dwarf class, conspicuous for the tufted habit, so to say, of the plants and the fine colours of the leaves. We made note of the following kinds: Duke of York has deep crimson foot-stalks to the leaves, the blade carmine-rose. Chelsea Gem is one of the most brightly coloured of all, and very attractive with its shades of crimson and carmine. Chelsea Gem, F. W. Moore, Duchess of York, Ladas, Lord Rosebery, and Tennyson, all having this dwarf habit of growth, were also noteworthy. We noticed also several of the newer Dracenas, such as Frederici, Jamesi, with narrow, graceful, chocolate and crimson leaves, and Lord Wolesey, whilst striking for its curious and distinct magenta-shaded foliage is Strobilanthes Dyerianus. Brugmansia suaveolens was flowering freely, its large trumpet-shaped, creamy-white flowers filling the house with their powerful perfume.

The fruit houses were filled with the usual selection of trees in the best of health, and Strawberries promise well for a splendid crop. Chief reliance is placed upon John Ruskin as an early kind.

A considerable extent of woodland surrounds the gardens, and one notices how well the Beech thrives here, forming splendid specimens, now in the full beauty of their spring leafage, whilst in a woodland drive of some miles is "The Beech Walk," an avenue, so to say, of Beeches, meeting overhead and forming a canopy of greenery, setting off the sombre-coloured Conifers and Yews that abound. We are pleased to see that this woodland drive has been opened up to give the many fine trees and shrubs some chance of showing their charming character. Here the lovely Silver Birch is thoroughly at home, sometimes standing by itself or backed by the heavy-coloured Yew. Large bushes of the common Barberry, the silvery-leaved Sea Buckthorn (Hippophae rhamnoides), Laburnums, Lilacs, and the Wayfaring Tree (Viburnum Lantana) are interesting, and suggest how still more delightful such a walk may be made by introducing other beautiful flowering shrubs, of which we have a countless number in gardens. Several trees of the double-flowering Cherry were in full blossom, every branch wreathed with the pure white, double rosette-like blossoms, as if snow had clothed them with a pure white covering. In full flower also were the Bird Cherry, the Chestnuts, the red flowered varieties just tinged as yet with colour, the Laburnums, and such things as the common Spindle tree (Euonymus europaeus) to brighten the autumn landscape. Here and there the mass of bright green is relieved by excellent specimens of Picea Morinda, and Abies Douglasi succeeds remarkably well. The Conifer family, as a rule, has fared badly during the past winter. Here one sees many browned trees, some dead, others so injured as to be worthless. What a lesson the winter has taught planters in the careful avoidance of everything not thoroughly hardy. Trees only just arrived at full maturity have been killed, whilst many things we know to be perfectly hardy amongst flowering trees and shrubs are neglected. By this drive we noticed a large tree of the curious Cytisus Adami. The tree bears racemes of purple and yellow flowers, these appearing not only on the same specimen, but on the same branch. There are a certain quaintness and charm in old examples of this strange supposed hybrid. In the garden and woodland, purple-leaved Beeches impart welcome colour, sometimes against tender green foliage or a Lebanon Cedar, whilst in the garden proper, Pyrus malus floribunda was a mass of bloom. This is one of the most delightful shrubs ever introduced. The graceful tender shoots are smothered with bloom, tender pink, except the crimson buds. A large selection of Spiraeas is grown, and one sees also such charming features as Daffodils planted in a natural way in the grass, an arcade of Roses, Vines, Clematises, and other climbers, while the more stately, hardy, fine-foliaged plants, as Heraclium giganteum, receive attention.

TREES AND SHRUBS.

TRUMPET FLOWERS.

(BIGNONIA.)

THE hardy species of this large tropical genus of climbers are invaluable, being so graceful in growth, showy in flower, and vigorous. There are three kinds thoroughly hardy against sunny walls in almost every part of these islands. They are *Bignonia radicans*, *B.*

Trumpet Flower will run up and cover a wall 40 feet high. It is useful also for covering arbours, pergolas, and the like.

*B. GRANDIFLORA* (see illustration), a Chinese plant, is more tender than *B. radicans*, and by no means so common. It is much showier when in bloom, the drooping flowers being twice the size, of a bright orange-scarlet, and produced in large clusters. Its foliage, too, is larger, but the plant rarely grows so vigorously in this country as *B. radicans*. It is a glorious object in bloom and worthy of the best position on a warm sunny wall.

*Bignonia grandiflora.* Engraved for THE GARDEN from a photograph sent by Miss Willmott.

*grandiflora*, and *B. capreolata*. The first two are strictly species of *Tecoma*, but are most generally known as *Bignonias*; therefore the name is retained here.

*B. RADICANS* is a native of the North American States, and is an old garden favourite. Its long wiry stems send out roots like Ivy, and so cling to walls or any support. The pinnate foliage is graceful, and in late summer the shoots are terminated by dense clusters of showy trumpet-shaped scarlet and orange blossoms. There is a variety named major with larger flowers of a paler tint, and the foliage also is more robust. A strong plant of this

It was introduced at the beginning of the century, but never seems to have become very common.

*B. CAPREOLATA*, a true *Bignonia*, is a native of the southern parts of North America, and is quite hardy in all but the coldest parts of England. It is commonly grown as a greenhouse climber, but it succeeds well against a warm wall. It has heart-shaped leaves ending in curly tendrils like a Vine, which enable it to climb high. The flowers, of a true trumpet shape, are large, reddish yellow, and produced, not in clusters, but singly. Given a sheltered spot against a sunny wall, it is a most satisfactory plant, and almost an evergreen.

Other *Bignonias* from temperate countries, such as *B. capensis* and *B. australis*, might be planted against sunny and sheltered walls in the south, where they often flower as freely as in a greenhouse.

TREES AND SHRUBS IN SUSSEX.

ONE would be almost inclined to think that after such a severe winter many of these would fail to bloom. Such, however, is not the case, if we may judge from those already in flower or that have faded and gone. The early-flowering *Spiræas* such as *confusa* and *Thunbergi* were never more beautiful, the long, slender branches of the latter being covered with their tiny clusters of white flowers, which hang gracefully to the ground. *Deutzia gracilis* with me has suffered somewhat, as on the stiff soil the growth does not always get thoroughly ripened; some of the shoots that were well ripened are blooming their whole length and bearing graceful spikes from 2 feet to 3 feet in length. We next come to *Kalmia nana*, with its delicate-looking flowers. *Andromeda Cates-bai* made shoots last season from 2 feet to 3 feet in length, and these are now clothed with clusters of Heath-like flowers their whole length. This shrub is well worthy of more extensive cultivation, considering it is so hardy and presents such a graceful appearance when in bloom. Wherever Heaths will grow this will also thrive amazingly, though it delights in rather more moisture. Large sprays of it remind one of Solomon's Seal at a distance, though on closer inspection it will be observed the flowers are produced in clusters hanging from the undersides of the shoots.

*Azaleas* have never been more beautiful than they are this season; the hundreds of plants alongside the drives and woodland walks quite scent the air with their delicate perfume. *A. mollis* is particularly fine this year, there not having been any late-spring frosts to injure the bloom. The lovely shades of this interesting section are so pleasing, that none could help but admire them. Ghent varieties also look well just now. *Azalea amona*, which is considered by some to be too tender to be planted in the open ground, has passed through the late severe winter almost uninjured, and is now one mass of flower. This plant is much more hardy than some people think, being less liable to injury than either the *Laurustinus*, *Escallonia*, *Arbutus* and such-like plants. *Rhododendrons* of the early-flowering section, such as *R. catawbiense*, *ferrugineum*, *hirsutum*, *dauricum*, *ciliatum* and other dwarf-growing kinds, have all withstood the frost well. These are charming subjects for small beds or the rock garden where the soil is of a peaty nature. Hybrids in a great measure have been but little injured, though a few of the more tender early-flowering varieties had their buds killed, and some of those with rough foliage had the leaves pinched by the frost. One of the most interesting trees here at the present time is a large specimen of *Halesia tetraptera*, which has grown to the height of about 20 feet, its long, slender branches being clothed with Snow-drop-like flowers. How seldom do we meet with this plant except in a small state, and seeing it is so hardy and introduced for so long a time, the wonder is that it has not become more common. *Aralia Sieboldi* has suffered much this winter—so much so, indeed, that I fear large plants which have withstood the frost for the last twenty years are completely killed. Some of the Palms have withstood the frost and are now sending up their flower-spikes. *Magnolias* do not seem to be injured in the least and are flowering as freely as usual. H. C. P.

**Double Lilacs.**—Differences of opinion may exist as to whether double or single-flowered Lilacs are the more beautiful, though for my own part as garden shrubs I prefer the single kinds. One of the best double-flowered kinds is certainly Leon Simon. A good double white variety with exceptionally large blossoms is Madame Lemoine, while a suitable companion, but with single flowers

is Madame Legraye, which is now largely grown for forcing. It is less vigorous than some of the others, but is in every respect a very desirable form. So is Souvenir de Louis Spath, whose massive clusters of richly coloured blossoms cause it to be singled out at once from among its associates. For forcing where the plants are brought much nearer to the eye, and consequently the duplex style of the flower is more apparent, these double Lilacs form a pleasing variety, but there are too many sorts.—T.

## GARDEN SKETCHES.

### CHAPTER XII.

Thanks to the human heart by which we live,  
Thanks to its tenderness, its joys, and fears;  
To me the meanest flower that blows can give  
Thoughts that do often lie too deep for tears.

WORDSWORTH.

NOVEMBER 3.—A few crisp mornings of white frost have brought us into November. The cool, brisk air was pleasant after such continued warmth, and just gave the sense that summer was indeed over, and that the flowers still left with us were precious, because so soon to haste away. Nothing was really harmed, only the fear awakened that the next touch might be blackening to tender plants, so that all should be housed or made safe in the ground by leaf-mould or other protection round the roots. The Ivy-leaved Geraniums have been lifted and potted, and in their place Tulipa Gesneriana has been planted. These should be fine next spring, with the border of silvery-leaved Cyclamen and pale blue Hyacinths. The crimson Fuchsia bed has had the soil renewed by fresh loam and leaf-mould, and it, too, is filled with scarlet Tulips and young plants of Forget-me-not added to carpet the ground in early spring. Then the bulbs of Tulipa Greigi which were lifted in the month of June have been replanted among the white Fritillaries, as this was found to be a charming companionship in the month of April. A few extra bulbs of Chionodoxa Luciliae gigantea and the larger Scilla bifolia and Narcissus Bulbocodium have been added to the rock garden, where the earliest blossoms of the year are to be found in sunny nooks.

And now when the lovely tints of fading foliage are gone, and the strong winds have swept each leaf away from the grey tracery of branches overhead, our thoughts turn naturally to the hidden treasures in the earth, the bulbs with sleeping blossoms, that will wake with the returning days of spring. Our gardens are never without a promise, even in winter's darkest hours, and this is one of a garden's greatest charms, its perpetual expectancy and onward glance to blossoms and to fruitage of which as yet the dormant buds may be all that is visible. No doubt the disappointments of "gardening" are many. There is much waiting, and often our hopes are frustrated by cruel frost, or storm, or drought, or insect pest. But difficulties overcome, courage and perseverance strengthened, and patience cultivated, bring powers of the mind that blossom into more lasting flowers, that cannot be swept away by chance or change.

When our gardens pass from us we are apt to think that our labour is lost and swept away, but it is not always thus, and that others should reap where we have sown is, mayhap, a richer gain than we imagine. The circle of our life must ever be enlarged by those to whom it reaches, for it is not by what we have done for ourselves, but by what we have done for others that the best days of our life must be counted.

NOVEMBER 15.—This morning brought a lovely sight, that of a golden-crested wren

bathing among the blossoms of the Cape Hawthorn (*Aponogeton distachyon*) in the fountain basin. A few stones hold the plant in position, and it was upon one of these that the exquisite little creature stood, and boldly dipped and splashed, itself scarce larger than the flowers, and like a blossom with wings. Now, as the hours of daylight shorten, the old Monthly or China Roses gleam out in all their beauty. Shades of brightest crimson, cerise, blush, and creamy white, all mingled together, give a brightness of colour not equalled by any other out-of-door flower at this late season. In sheltered spots there is hardly a day during winter that a few buds cannot be found on these Roses, while they are the earliest to respond to the first warm days of spring. Their cheerful shining leaves are retained until pushed aside by the fresh swelling buds, so that they have never the bare, winter aspect of other Rose trees. One can scarcely call them perfumed, and yet they have a subtle, delicate odour and scent of freshness which is all their own and very delightful. The old Blush Monthly Rose has been well-nigh a century in our gardens, having been brought to this country in the year 1796. Like other old-fashioned plants, these Roses were set aside to make way for the "bedding-out" system, but within the last few years the love for them has been again aroused, and happily so, for these Roses full of variety and good qualities are a garden in themselves. The Chrysanthemums in the flower border are well in blossom now. Grown in their free, unbudded state they are valuable for indoor cutting, being so much more graceful for vases than one large flower on the top of a stick, the cultured fashion of late. The earliest Hellebores are beginning to lift up their flower-buds. It is pleasant to push aside the leaves and peep at the nests of flower-buds clustered together, some enclosed in their pink sheaths only emerging from beneath, others risen above the ground with pure white buds, all promising a harvest of blossoms for months to come. They are planted everywhere, here and there in the herbaceous border for the sake of their evergreen foliage in winter, in the rock garden, in groups among a bed of American plants, in the fountain garden, and in the walled garden, where the seedlings spent their first year after being planted out. But no matter how numerous they are, there never seems one too many, so highly are they prized in the dark days of winter.

And now as the year draws to a close in which we have recorded the passing of the flowers from week to week and month to month, let us for a moment glance backward and see how the golden thread of blossom has been from the very first interwoven with the web of life. We are prone to forget what the great philosopher tells us, that "God first planted a garden, and indeed it is the purest of human pleasures." In sacred history, flowers are alluded to as emblematic of spiritual growth in man, and looking back through profane history we notice how they have ever mingled in rites and ceremonies of an emotional character. How much the Greeks were indebted to flower and foliage for their decorative art, we learn in the beautiful forms and curves visible throughout their designs. Even in the present day many of our pillars still wear the noble Acanthus leaves with which the old Greeks loved to clothe the capitals of their stately columns. From the earliest ages poets have sung of flowers, and we can all remember the ancient myths in which gods and goddesses were transformed into trees and blossoms. In the waving corn-fields the bread of the world is silently made. From the shade of

the forest our shelter is given. The timber grown there in stillness supplies our every need, until at the end it bears us to our last resting place. The buried flora of past ages blossoms afresh for us in the kindling warmth that awakens new buds and flowers in our hot-houses, so that flowers dead thousands and thousands of years ago can light our earth stars for us now, and the energy conserved for long ages of time in the vegetable blackness of coal leaps forth into flame and gives us the great steam force which has extended our nation and language until it circles the world, and has brought to our shores the richest produce of other lands. Accustomed as we are to the fruits of far countries and all the produce of warmer climes, we never pause to remember that they are borne to us, at least in far the greatest quantity, by the force of a dead flora whose leaves and blossoms once shimmered in the sunshine, and then sank into darkness and oblivion for ages of time.

There are in life many pursuits, many things precious and beautiful, that can only be followed or possessed by the few; but the love for, and enjoyment in flowers is free and wide as the world itself. A queen in her palace garden may walk amid Roses and Lilies, but she cannot receive more pleasure from them than the humble cottager in some far-off lonely vale who has only one "Rose looking in at the window," and whose Lily stems lean against the time-worn walls of her lowly dwelling. A king may have his marble halls filled with rare plants from southern shores and his table adorned with exotics, but there may be a coat of mail beneath the royal robe; while the poor city weaver, free and fearless in his smoke-dimmed chamber in the narrow, darkened street, may enjoy with a right royal heart his bunch of golden Daffodils, set in an old brown jug, but bringing with it the scent of hedgerows and song of lark and flickering sunshine over hill and dale, remembered from his mother's home in days gone by. The finest work is oftentimes formed with the simplest tools; so it is to the poor Manchester weaver, who found time amid his daily toil to love and tend his flowers, that we owe Narcissus Horsfieldi, that king among Daffodils.

And now the after word. Let no one think that he cannot graduate in the school of gardening and pass from it the richer of its many lessons. Perhaps one little flower, the "crimson-tipped Daisy," can tell us what some of these lessons are. Placed wherever it may be, on some lone hillside, buffeted by storm and drenched with rain, trodden under foot in the dusty byeway, unseen and forgotten in some shady copse, shorn of its flowers in some velvet lawn, it is always dauntless, accepting its surroundings no matter how adverse, and so turning for ever a fearless eye to heaven.

L. A. L.

### NOTES FROM A SUBURBAN GARDEN IN SOUTH DUBLIN.

AFTER a winter phenomenal in its length, we can now form some idea as to where we are, and the general verdict about here is, that we have escaped much better than we expected. In my own little garden (and elsewhere) Veronicas of the Andersoni type are utterly destroyed. Of *V. Hulkeana*—which was never injured before—but one plant remains, and that sorely crippled. *V. pinguifolia* is untouched, also *V. salicifolia* (?) and *V. Lavandiana*; the latter was covered up with snow, which doubtless saved it. Similarly, *Pittosporum Tobira* is almost killed, except some branches which lay on the ground and are uninjured. *Olearias* (*stellulata* and *maerodonta*) are also almost exterminated not only here, but at Mount Usher, Co. Wicklow; but lately I saw

at Killiney large bushes of the former absolutely untouched and bursting into bloom. These are growing in a north border where, I am told, they get no sun for six months of the year. Is this the reason they have survived when others have been destroyed? A young plant of *Eucalyptus* is breaking up strongly from the root, while an old *Heliotrope* which has been for years under the sill of my drawing-room window is coming up as well as usual. A healthy little clump of *Gentiana verna* seemed to enjoy the severe winter, and has yielded about fifty flowers. Three or four inches of ice on my 1½-foot deep Lily pool have done no damage to two of *Marliæ's Nymphæas* (*N. Marliæa Chromatella* and *N. odorata rubra*). Numerous flowers and buds are visible on the former. *Sparaxis* and *Ixias*, which were sedulously protected with twigs and hay, escaped pretty well and are now coming into bloom. *Cordylines* are considerably browned, but the central core of leaves is in all, or nearly all, instances uninjured. *Escallonias* have felt the cold considerably, *E. montevidensis* worst, then *E. pterocladon*, while the old *E. macrantha* has become for the time a deciduous shrub, but, with that exception, seems none the worse. This change from evergreen to deciduous is noticeable in other things, such as *Abelia tritloræ*, *Passiflora cœrulea*, *Edwardsia grandiflora* to a less extent, &c. Beyond a very slight scorching, *Choisya ternata* has come well out of the ordeal, and is now covered with its lovely scented flowers; and a similar remark is true of *Rubus deliciosus*, which is blossoming better than I ever had it before. The hardiness of these two is, I think, now beyond dispute. *Ficus repens*, which covers the back of my little stove, has for some time crept out and over the wall outside, and last winter was unable to kill it. Another grand plant which laughs at frost and snow is *Rodgersia podophylla*, as also its comrade and congener, *Saxifraga peltata*, which has this year been literally bristling with flowers. It will, I think, be interesting and instructive to hear what have survived and what destroyed in various localities and under various circumstances, so I venture to contribute my mite of information. G. P.

## FLOWER GARDEN.

### AQUILEGIAS.

THERE are few hardy perennials more generally worthy of cultivation than the *Aquilegias*. Perfectly hardy and enduring in so far as the true perennials are concerned, and in most soils these beautiful plants year by year increase in beauty and number of flowers produced upon individual plants. This is especially true of the larger kinds that are more fitted for the border than of the dwarfier alpine forms. With the exception of *A. sibirica* all the species have drooping flowers, and this fact, combined with the delicate connection of the stalk with the blossom, imparts an exceedingly graceful bearing. *Aquilegias* are best raised from seed, taking care that the supply of the choicer kinds, for example, *A. alpina*, *A. glandulosa*, *A. cœrulea*, and others is obtained from some reliable source. These flowers are so readily cross-fertilised by insects, that it is only with care that seed true to its kind can be secured, either by covering up a whole plant with fine gauze, or a few pods according to requirements. The ease with which these flowers are fertilised has resulted during recent years in a most charming race of plants, among which are many exceedingly distinct and beautiful shades of colour. The propagation of any particular plant of special merit can only be accomplished by very careful division, and preferably in the spring-time. This may also be done early in autumn, say the end of August and early September, but never late in the year. Such divisions are frequently safer if planted in boxes of cocoa-nut fibre and stood in the open

in a somewhat sheltered spot; this is to be preferred to potting and placing in frames, and particularly is this true of the more delicate and rare kinds, either species or hybrids. A deep sandy loam, fairly rich, will suit most kinds well. Some of the taller kinds, and notably *A. chrysantha*, I have never seen finer than when grown in a good fairly stiff loam. In this the plants were most vigorous, attaining in the third year to nearly 3½ feet high and fully as much through, and bearing many hundreds of blossoms and buds. Such fine examples of the larger kinds

1 white *Aquilegia*.

can only be obtained by letting the plants alone. Indeed, these plants are not benefited by transplanting, but generally the reverse, and invariably so if large clumps in the open. Seedling plants of these *Columbines* transplant readily in a young state and well enough for a year later, but to obtain the best results the seedling plants should when large enough be planted at once into their permanent positions. This is equally true when grouping the dwarfier alpinæ in the rock garden as when planting larger beds in the flower garden.

There are many distinct and beautiful kinds, the following being among the best: *A. alpina*,

deep blue; *A. cœrulea* (Rocky Mountain *Columbine*), flowers sky-blue and white, a most charming kind for the rock garden or for pots; *A. chrysantha*, yellow, 3 feet to 4 feet, a most handsome bush when in flower; *A. formosa*, bright red, very distinct and effective; *A. glandulosa*, an exquisite and handsome species with very large deep lilac-blue and white flowers, rarely more than 9 inches high, a grand plant for the rock garden or for pots in a cool house; *A. olympica*, delicate mauve-blue and white, quite a distinct type, height 1½ feet; *A. pyrenaica*, lilac-blue, very effective, best regarded perhaps as a biennial, 9 inches to 1 foot high.

Apart from these there are many varieties, to say nothing of an almost endless supply of hybrid forms of *cœrulea*, *canadensis*, *californica* which provide us with a marvellous array of new, distinct, beautiful, and varying shades of colour. Many of these hybrids are beautifully adapted for pot culture for conservatory decoration, and under glass are decidedly pleasing and effective. E. J.

### NOTES ON HARDY PLANTS.

**Campanula tridentata.**—The first flowers opened on May 14. They are posed salver fashion, but in shape are half cup and half star, *i.e.*, there is a distinct cup of deep purple that could scarcely be covered by a shilling; then the segments of the corolla, which are of a more red-purple, are sharply bent back, and so give the star-like effect. The whole flower may be 1½ inches across, the plant is but 3 inches high, and it has stood quite exposed facing south and at an elevation of 2 feet from the Grass level. Here we have something fresh, and certainly a plant of the first rank. Where the tridentate quality comes in I do not see just now, but I fancy the early radical leaves are so formed at the blunt ends.

**Pœonia Witmanniana.**—This is now in flower, proving itself to be one of the very earliest species. It has large creamy single flowers, the cups pretty well filled with golden stamens or anthers somewhat pink tinted. Its perfume is a valuable quality, though some might consider it a little too strong or with too much of the Valerian flavour. I fancy this desirable *Pœony* will shortly be cheaper, and nothing, one would think, can then bar its wide cultivation.

**Silene chromodonta.**—In a similar position as the above *Campanula* grows a two-year-old specimen of this rare variety, or possibly species, and yet it is but 3 inches across. Though so humble, now it is in flower it is exquisite, and the very ideal of neatness and purity and what an alpine in cultivation should be, for do we not find that many species as seen wild become so greatly changed under cultivation as to quite change our ideas of their fitness for our gardens.

**Rosa glutinosa.**—My specimen is three years old and in its second year *in situ*. I mention this because the fact of acclimatisation has always something to do with periods of flowering. I have got to make a somewhat bold statement in regard to this dwarf species, and that is, that it is by far the earliest *Rose* to flower of all with which I have had any experience, which (the experience) has mainly been with species. The flowers open this morning must be quite a fortnight earlier than those of *R. rugosa* in the same garden. The flowers are the size of a half-crown, bright rosy carmine, and powerfully scented in the way of the old *Damascus* or the true *attar Rose*. The name is a very good one (*Sieb. and Sm.*). The whole of the young foliage is not only sticky, but glistens with the exudation. Stature of three-year-old plant, 18 inches. Perfectly hardy.

**Saxifraga minuta.**—This is worthy of notice, first because it is quite hardy, next because it is beautiful, and again because, for all its large genus, it is peculiarly distinct. It belongs to the

same group as *rotundifolia*, and it is especially in regard to the members of that set that the fitness of its name comes in, for otherwise it is not so minute a species as more than a score that could be mentioned. It is flowering at a stature of 5 inches, but the radical herbage sits very low. I have tested it in the past hard winter, and it has come safely through. The flowers are large, snow-white, and so full as to seem almost double in the corolla; they are laxly borne on stems beset with bright cherry-red bulbils, originating independent of flowers. These bright wart-like organs adhere a long time, and add much to the decorative value of the frail and succulent plant.

Woodville, Kirkstall.

J. Wood.

#### IN THE GARDEN IN MAY.

WHAT a wealth of interesting plants one finds in the hardy flower garden just at present. Amongst the various yellow-coloured kinds we have the golden Globe Flowers, or *Trollius*, including *T. europæus*, pale yellow, and its creamy white variety, though the latter does not bloom until the type has almost finished. *T. asiaticus* varies in different shades of golden yellow, and is taller than *T. europæus*. *T. asiaticus* fl. *croceo* is a deep rich orange. *T. Ledebouri* and *T. Loddigesii* appear to be forms of *asiaticus*, as is also *T. giganteus*, whilst *T. americanus* is very much like a tall form of *europæus*. *T. napellifolius* is very distinct, its rich yellow flowers rising profusely 6 inches higher than its compact tuft of pretty foliage. *T. acaulis* has deep orange, semi-double flowers, produced singly on sturdy stems only 9 inches high; the outer petals, slightly tinged with green, are toothed at the edges; this is a very distinct plant indeed. *Caltha palustris* fl. *pl.* is very bright just at present, following immediately in the wake of *C. palustris monstrosa*, which is fading as the former commences to flower. *Geum minimum*, *G. hybridum*, and *G. arcuatum* are also beautiful; the two first are different shades of orange, the latter yellow. A plant very much like a yellow *Geum* is *Sieversia elata*, which throws up quite a number of spikes bearing numerous yellow flowers. *Chrysogonum virginianum*, *Arnebia echioides*, *Ranunculus graminifolius*, *R. speciosus* fl. *pl.*, and *Hemerocallis minor* or *graminifolius* are all yellow May-flowering plants, whilst *Lithospermum hirtum* and *L. canescens* should certainly not be forgotten. These two perennial Gromwells are perfectly hardy and form tufts of deep yellow flowers. A good rock shrub is *Berberis rubricaulis*, like a dwarf form of *B. empetrifolius*, with small round yellow flowers.

Amongst Irises I find *longipetala* in bloom, with its chaste Orchid-like flowers, the standards pale blue and the falls heavily pencilled with the same colour on a white ground, with a touch of orange towards the base. *Iris cristata* is a mass of lovely blue, and a novelty is *Iris bosniaca*, which has large pale yellow flowers; this is a dwarf rhizomatous sp. and a good plant. *Iris macrospira* var. *flava* is scarcely definable, so delicate is the delicious creamy flower (with its faint crimson markings), which is borne on a stem 6 inches high, and is well worth the glass protection which shields it from the severe north-easterly gales at present prevalent. Another beautiful Iris in flower now is *I. Korolkowi violacea*.

Two beautiful fine-foliaged plants are *Rodgersia podophylla* and *Podophyllum Emodi*; the former, with its handsome, bronzy leaves, makes an excellent pot plant, and as such is very useful for decoration. The latter has dark green leaves, prettily marbled with chocolate; its milk-white flowers are just and the seed-pods are still green, but will look when ripe like an egg-shaped Cherry. *Tritoma pauciflora*, a very pretty yellow-flowering sp. with pendulous spikes, and *T. Tucki* are May-flowering. A good new plant is *Incarvillea Delavayi*, which has a spike 1 foot high with already two flowers—more to follow, of a bright rose colour, with yellow throat. The individual flower is of the same shape almost and quite as large as that of a *Gloxinia*, but the throat is more congested. *Trillium grandiflorum* deserves all

that can be said of it. *T. erectum album* is also very pretty and distinct with its greenish white flowers, with a conspicuous black pistil. *Nymphaea Laydekeri rosea* opened its first flowers on May 16 under glass. *Cyclamen repandum* has a profusion of bright crimson flowers all through May. *Pedicularis canadensis* bears curious, Ajuga-like heads of flowers, varying in colour from pale yellow to red. *Camassia Cusickii*, with its pale glaucous foliage and grey-blue spikes (3 feet high) is very handsome. A rare plant is *Onosma Borigia*, which has pale sulphur-coloured flowers, borne on a very robust spike. *Eremurus Elwesianus*, opening its first few flowers on an already 9-foot spike, promises a great deal of beauty for some time to come, considering that the flower part of the spike is quite 3 feet long. A good dwarf Lupin is *nutkanus*, only 18 inches high. *Lithospermum prostratum*, notwithstanding the recent severe winter, has made heroic efforts to recover itself, and is now in many places a sheet of that exquisite blue which is also to be found just at present in *Gentiana verna*, *Myosotis rupicola* and, a little later, in *Gentiana bavarica*. *Arenaria montana*, or, as I believe it to be, *Arenaria grandiflora*, is showing visible signs that it is going to be as good as last season—mounds of the purest white. Some of the *Puey* tribe are also in flower. *P. Wittmanniana* has a few of its pale yellow flowers, but they have been a trifle damaged by the wind. A bed of *P. tenuifolia* is magnificent, numbers of its crimson flowers resting upon a cushion of the most finely cut and elegant foliage. *P. decora elatior* is a handsome plant, with large rosy crimson flowers and very distinct and ornamental foliage. *P. peregrina compacta* is also a very good plant. Amongst *Dodecatheons* may be found *Jelleyanum*, *integrifolium*, *Clevelandi* and *media* in variety. *D. Clevelandi* is very distinct, pushing up its pale green leaves very early, and now its spike of pretty dark centred flowers with white upturned petals tinged more or less towards the tips with rose. The varieties of *Phlox setacea* and other rock kinds, *Aquilegia coerulea*, *A. canadensis*, and *A. flabellata alba* are pretty. The last only grows 1 foot high, and has white flowers with a slight tinge of blue in them. Many mossy *Saxifrages*, *Scillas* of the *campanulata* and *pyramidalis* section, *Centaurea montana* in blue, white, sulphur, red, purple, and flesh colours are also in bloom. *Mertensia alpina* has flowers something like those of *M. sibirica*, but the habit is totally different. *Pentstemon Menziesii* that has stood out all winter is now bearing its dark blue flowers. *Silene pennsylvanica*, in habit like *S. virginica*, but dwarfer, with its pale pink flowers, is very pretty, and amongst the *Candytufts* might be mentioned a very dwarf compact-growing species called *Iberis pinnata*, which only rises a few inches above the ground and forms quite a snowy cushion.

These and many others after the severe winter we have just experienced prove conclusively that there is a great deal in hardy plants. G.

Newry.

**Narcissus culture in the Isles of Scilly** (page 356).—The total run of the ten houses at Tresco utilised for the forcing of *Narcissi* should have been given as 1500 feet instead of 15,000 feet.—S. W. F.

**Seedling Daffodils.**—Mr. J. Cornhill's note (p. 338) is of much interest as touching upon the raising from seed of double *Narcissi*. This has apparently been thought very difficult; at all events, it has been but little practised. But some double kinds, e.g., the old *Telamonius plenus*, or double yellow of gardens, commonly both yield fertile pollen and show a perfect stigma. I have myself raised and flowered seedlings, both crossed and uncrossed, from the double yellow and the double *cernuus*. The latter inherit a weak constitution, and are beautiful, but valueless. But from the old double yellow *Daffodil* I have, just as Mr. Cornhill has, some strong and handsome seedlings. My best are flowers from the double yellow fertilised by pollen of *N. poeticus ornatus*, and are practically new forms of double *N. incomparabilis*. There is probably a future of some interest and

value for double seedling *Narcissi*. I would, however, suggest to Mr. Cornhill that he is to some extent wasting time and talent in employing the Tenby *Daffodil* so largely as a seed or pollen parent. This kind may do well in his particular soil and climate, and it is true that it is most useful and pretty where it succeeds. But it has been most disappointing to a great many growers, private and professional, the plant dwindling and dying out in many soils. I could tell Mr. Cornhill of large trade growers who have either lost their stock or kept it only by frequent exchange and importation of fresh bulbs. In my own district it will not live in cultivation, keeping in fair health without increase on grass only; and I have long since ceased to use it for pollen or seed. In crossing Tenby and *cernuus*, Mr. Cornhill is marrying two feebly or uncertainly constituted parents, and the offspring, though it may be pretty in his own garden, is not likely to be of permanent value in gardens at large.—G. H. ENGLEHEART, *Andover*.

**Calochorti.**—It would be well for all lovers of flowers to see a bed of *Calochorti* at this present moment, and to become aware of the ease with which they can be grown. I have acted strictly on information which was given to me by Mr. W. Wallace at Colchester, and I can now substantiate everything he said. The great point is to give them a good long season of rest, and as you have to do with bulbs this is very easily managed by taking them out of the ground after they have blossomed and keeping them in a drawer for ten or twelve weeks. This makes all the difference in the world to them in point of success. They should have very light soil, of which leaf mould and sand are two constituent parts, and I am told (this, however, did not come from Mr. Wallace) that they do better in shallow soil than in any other, and that it ought not to exceed a depth of 7 inches or 8 inches. They need very little attention, and their bright colours, fantastic shapes and delicate markings are always much admired.—K.

#### BALSAMS.

MR. W. B. HEMSLEY mentions in a paper of his on the vitality of seeds in *Nature* that Balsam plants are credited with producing more double flowers when the seed is old. Experience has shown this not to be strictly exact. Doubtless comes chiefly from strain, and although poor culture, by somewhat starving the plants in a young state, may conduce to the production of imperfect double blooms, yet, as a rule, seed of the freshest reproduces its kind even of the most double description of flowers. Some years since I used to grow Balsam plants in very large quantities, occasionally a portion from new imported seed to obtain new colours, but generally from own-saved seed of the previous year, and always found the product to be of the finest double form. That is, I think, too, general experience; indeed, it is doubtful whether the great bulk of Balsam seed sold annually in this country and at once sown is not of the previous year's crop, and everyone must admit that we have in this way the finest double flowers on Balsams conceivable. Once such a favourite pot plant, the common double Balsam has had to give place to *Begonias*, *Gloxinias*, and other more gorgeous plants. Still few of the novelties can produce such a pleasing handsome tree-like plant as comes under good culture from the Balsam. The natural habit is pyramidal and branching, the flowers and foliage well balanced, and if branches seem too thick the smaller ones can easily be thinned. In this way in a comparatively short time with but a little or even no artificial heat and in 8-inch pots it is possible to have plants that are from 20 inches to 24 inches in height, of admirable proportions, and most beautifully flowered. Individual Balsam blooms may not be very graceful, but the plants if well grown when in full bloom are very much so. The branches are not, happily, adapted for cutting, hence these plants are usually spared that treatment which falls to the lot of so many other things. Balsams,

too, give us great variety. I once grew eighteen distinct varieties according to the colours or markings of the flowers; it is very likely there are even more now in commerce. Still, a collection of some twelve distinct varieties suffices for all ordinary purposes. The self colours are the most effective, especially white, pink, magenta, scarlet, violet, and there are some pleasing Carnation-flaked and speckled varieties too, and these have their admirers. Not many persons seem to appreciate Balsams as bedding plants, and yet well grown and upon a carpet of some neutral tints they are wonderfully pretty. I always found the best results from plants allowed to become very stout, then transplanted direct from the frame to the open ground. When first put into small pots and later turned out of these with balls of soil and roots the usual effect was to produce massive bushes of branch and foliage, but not much bloom. Balsams grown outdoors on good soil are very long bloomers, and if put out thinly on to a base of some dwarf plant, show off their individual features admirably. For this form of culture I prefer to sow seed in a cold frame or greenhouse about the first week in April, and thinly. The seedlings should be well exposed to light and air when a few inches in height, so that when planting-out time comes they may be some 6 inches high and have stout stems to resist the attacking slugs.

A. D.

## THE ROCK GARDEN.

## IX.

MAY 23.—The hot weather has been followed by cooler temperature, but, nevertheless, the number of rock plants now in bloom is very great. I will not, therefore, attempt to give anything like a complete list of the flowers which have opened last week, but will mention only the best of those I have observed. As in my previous notes, the flowers here mentioned as being in bloom are only such as have been kept out of doors all the winter, and are mostly growing in various rock gardens in different parts of this county (Devon), and although in some cases the flowers may have opened prematurely and in others a little later than their usual season, the names given will, on the whole, give a fair idea of the kinds that are blooming together, and might in the rock garden be grouped together with good effect.

## CHOICE PLANTS.

As the smallest and choicest plants deserve the most prominent positions in the rock garden, I will mention them first. The following were blooming here in Exeter during the past week: *Dianthus intermedius*, *D. alpinus*, *Androsace cylindrica*, *A. glacialis*, *Myosotis rupicola*, *Edraianthus serpyllifolius*, *Haberlea rhodopensis*, *Ranunculus Thora*. As none of these are fast growers, they may be planted closely together. The first named, *Dianthus intermedius*, is a very rare and distinct variety, somewhat resembling *D. glacialis*, but it seems more compact and free flowering. *Dianthus alpinus* is more generally known, and though by no means a rare plant, its large bright pink flowers, produced in masses on very short stems, are so beautiful, that this species will always be considered a "gem of the first water" even in the most select part of the rock garden. It is a decided lover of limestone, and the soil should receive an abundant admixture of that material. *Androsace cylindrica* is decidedly rare. It is only 2 inches or 3 inches high, and its small white flowers are produced on slender, hairy stems. The plant referred to has for the last two years occupied a narrow crevice filled with little soil, but an abundance of limestone chippings, and on the west side of a rock. Its flourishing condition in that position proves

that it is well suited. *Androsace glacialis* seldom lasts more than two or three years, but it is an exceedingly pretty plant for the select part of the rock garden. Its native home is near the glaciers, and it requires, therefore, a cool position in the rock garden on the north side of a rock, but so placed that it can receive plenty of light without the direct sunshine at noon. The flowers are white, changing to light mauve. *Myosotis rupicola* is a very dwarf kind of Forget-me-not; its flowers are close to the ground and of a deep azure-blue. It thrives well on a level position. *Edraianthus serpyllifolius* should be planted sideways in a sunny position into an upright fissure where complete drainage would be ensured. It is, perhaps, the best of all the genus, its flowers being larger and of a brighter purple-blue than those of its congeners, which are not due to bloom till later on. *Haberlea rhodopensis* resembles a *Ranunculus* and should receive similar attention, *i.e.*, planted not upright, but sideways into a shady crevice filled with moist, spongy soil. Its flowers are of a bright mauve colour and very handsome. *Ranunculus Thora* is more curious than really pretty, but it is certainly very distinct from any other *Ranunculus*. The leathery, kidney-shaped leaves are comparatively large and more conspicuous than the small yellow flowers.

## DWARF ROCK PLANTS NOW IN BLOOM.

Beautiful rock plants of every description are blooming so numerous this week, that scarcely a shade of colour can be mentioned which is not represented by dwarf plants in the rock garden, without counting plants of medium and large size adorning the rougher parts and margins of shrubberies. All the plants here mentioned are actually in bloom at the time of writing, and as colour is a matter of first importance in the artistic grouping of plants, I will enumerate them according to their colour, and add here and there such brief cultural notes as space will permit.

WHITE FLOWERS IN BLOOM.—White appears to be the prevailing colour this week, and in most rock gardens that same colour is equally predominant. *Astragalus hypoglottis albus* trails close to the ground like a miniature Vetch. *Anacyclus Pyrethrum* forms a carpet of quicker growth; it has finely-divided leaves and white composite flowers with deep yellow disc. *Armeria maritima alba* (the white Thrift) is too well known to need further description. *Erinus alpinus albus* is an excellent rock plant, specially suited for dry rocks and sloping positions. *Androsace coronopifolia* is only biennial, but frequently seeds itself. *Androsace lactea* is more compact and requires less space. *Anthemis Aizoon*, with its silvery leaves and handsome large white flowers, is one of the very best rock plants and requires a dry, sunny position. *Saxifraga capillaris* and *Saxifraga Tazetta* are very much alike; they have round, entire leaves, each about half an inch in diameter, and white flowers on stems about 6 inches high, well adapted for a moist, level spot; and the same position would suit *S. tenella* and *S. arguta*. Of the encrusted section I have mentioned many in previous notes. *Saxifraga paradoxa* and *S. intacta minor* are among the best of the new arrivals. *Papaver alpinum* is an excellent rock plant and its large flowers mix well with other colours; it frequently seeds itself and likes a sunny position. *Nocea alpina* is a small crucifer with a carpet of dark green leaves. Another pretty crucifer is *Kernera saxatilis* var. *Boissieri*, only a few inches high, and with ovate lanceolate leaves. Very handsome rock plants are also *Ranunculus Segneri*, *Achillea Clavenna*, with large silvery leaves, and the very dwarf *Arenaria tetraquetra*.

RED.—*Armeria maritima Lauchiana* and *A. maritima* (Veitch's variety) are excellent rock plants, especially the latter, which has flower-heads of the brightest crimson. In a rocky border the scarlet *Delphinium nudicaule* is conspicuous, while in a sunny spot among the rocks *Anthyllis montana* has its red flowers conspicuously contrasted by its silvery foliage, and in a half-shady corner *Cortusa Mathioli* nods its head of purplish crimson flowers. Noteworthy plants of smaller size are *Lycnis alpina* and *Lycnis pyrenaica*, both doing well in small crevices. *Papaver alpinum rubrum*, the red form of the alpine Poppy, is also very handsome.

PALE PINK.—A useful rock plant of this colour is *Asperula carpathica*, which forms spreading tufts about 6 inches high and does well among the rocks. *Alsine rubra* is somewhat similar, and will grow in very poor, stony soil. *Leiophyllum buxifolium* is a minute shrub, very compact in habit. Many pale pink varieties are also contained among the dwarf *Phloxes* still in bloom. *Geranium cinereum* and *Geranium argenteum* should be in every rock garden, especially the latter, whose compact silvery foliage shows the flowers to greater advantage. Both love a sunny place. *Antennaria dioica* also makes a silvery carpet.

YELLOW.—Yellow was most abundant among the rock plants of a few weeks ago, but this week it is not well represented, at least not among the smaller kinds of rock plants. Several plants mentioned a week or two previous are still in bloom, but among new arrivals this week I have only noticed the well-known *Cypripedium Calceolus*, which does well in stony soil, *Potentilla sabarda* and *Ranunculus speciosus*. The last has large double flowers and is more suitable for rocky borders or margins of groups for larger plants.

BLUE.—*Linum alpinum* with its large pale blue flowers is very attractive, as are also the prostrate *Veronicas* now blooming, *viz.*, *V. rupestris* and *V. alpina*. The *Globularias*, too, deserve attention, their globular heads of deep blue flowers on erect stems being very striking. The varieties now fully expanded are *G. trichosantha*, *G. vulgaris* and *G. cordifolia*. *Polemonium humile* is an excellent dwarf and compact form well suited for level spots among the rocks, and lastly I would mention that glorious alpine *Columbine*, *Aquilegia alpina*.

ORANGE.—The only orange-coloured flowers this week are *Rhodiola linifolia* and *Erigeron aurantiacus*.

MAUVE.—This colour is well represented by the many dwarf *Phloxes* still in bloom. *Geranium lancastriense* also deserves notice, its striped flowers being very attractive; and last, but not least, I would mention that charming Himalayan *Androsace*, *A. sarmentosa*, without which no rock garden is complete, and which thrives luxuriantly if planted in a sloping position, and so arranged that its rosettes of leaves rest on stones and not on the soil.

PURPLE.—*Ranunculus pyrenaica* planted sideways into an upright fissure on the shady side of the rock presents a beautiful picture. *Erinus alpinus*, on the other hand, does best in a dry, sunny position. Of dwarf plants with purplish blue flowers and suitable for massing few are better adapted than the glorious alpine *Asters*, *Aster alpinus* and its varieties, *A. a. superbus*, and *A. a. speciosus*, while for a dwarf carpet of deep purple *Calamintha alpina* is well adapted. A very choice plant is also *Polygala Chamæbuxus purpurea*, which does best in moist peat on the shady side of a rock.

## MEDIUM-SIZED PLANTS IN BLOOM.

Before closing my notes on the flowers blooming this week, I will briefly mention a few larger plants more suitable to the bolder or rougher part of the rock garden or for borders than for planting on the rocks themselves. Among those blooming now are various kinds of *Dodecatheon* (purple, mauve, lilac, and white), which do best in deep moist ground; *Geranium sanguineum*, red; *Geranium Endresi*, with large mauve flowers; *Polemonium reptans*, blue; *Geum minimum*, orange; *Geum pyrenaicum*, yellow; *Convallaria majalis rosea*, *C. m. foliis aureo-striatis*, and *Dianthus hybridus Marie Parc*, white.

Etcetera.

F. W. MEYER.

(To be continued.)

## FLOWER GARDEN NOTES.

COLOUR IN PLEASURE GROUNDS.—Those who were responsible for the laying out and planting of many pleasure grounds in bygone days made as a rule provision for a great preponderance of greenery, so that the present generation has to put up with a maximum of foliage and a minimum of flower unless they are able to cut out the one and replace with the other. This bygone style of planting is the more regrettable in the case of those pleasure grounds that are rather thickly wooded and that have a fair amount of lawns. In such cases Laurels in variety and all evergreen shrubs whose flower is unimportant should only be scantily represented. Where flowering plants were introduced in these old pleasure grounds it is generally found that they are dotted here and there as isolated specimens among banks of evergreens instead of being grouped together in fairly large clumps so that they make a bold and effective display. The result of such a style of planting where labour is somewhat scarce (and the pleasure ground is the first place to suffer) is that these solitary flowering plants are apt to be so crowded by the surrounding foliage, that they are drawn up into long weedy-looking specimens that are not easily again restored into nice bushy stuff. I had an experience of this kind with a lot of hardy Azaleas some years ago, and draw attention to the matter now, because this is a good time so soon as they are out of flower to take any such weedy plants in hand. Extra room may be made for them by clearing away common foliage on either side, then long side shoots may be brought down with strong pegs as near to the ground as they may be required, using care in the operation to avoid splitting or breaking. The operation may be repeated if possible every second year, and the result will be not only well-furnished plants, but such an extension of the same on either side as to give a greatly increased breadth of colour to brighten up the surrounding greenery.

CARNATIONS.—The border Carnations are throwing up their flower-stems, and a little support will soon be necessary if the weather should prove at all rough. Where several stems are showing (not a very common occurrence this season) I like to put a thin stake down as near the centre as possible, and after fastening the matting to the same, to draw the stems loosely together, the result being support to the flowers and the avoidance of stiff, formal tying. Heavy-flowered Pinks, as Ernest Ladhams, will also need support. The above remarks as to the avoidance of formality in staking and tying are applicable to all herbaceous plants; indeed, the less of this work that is done the better, and a great point is the encouragement in all plants of strong, vigorous growth, so as to obviate the necessity for support. A great deal naturally depends on the season. In some years one cannot do without the support—in 1894, for instance, when strong winds and heavy, driving rains had a tendency to beat down nearly every plant that had not a stake of some kind. When there is an hour to spare, it will be well to get the

soil mixed for layering Carnations, but if the plants are rather close together, and one is likely to be obliged to get about among them a great deal in order to secure the flowers, it is not advisable to put the new soil on until the flowering season is nearly over. Also if the situation is dry and the weather seems likely to prove hot and dry, it is better to put a comparatively thin layer of the new soil nearly all over the beds rather than high heaps immediately round the plants. If the stock of Pinks is to be increased, and one cannot well have too many of such fine sorts as Snowflake, Her Majesty, and E. Ladhams, a bit of soil may be prepared for the cuttings and placed in an extemporised frame. Such a frame, both in the case of Pinks and Violas, is very handy, so that one can shade in hot sunshine until rooting has commenced. I prefer the cuttings of both Pinks and Violas on a south border with a little shade if necessary rather than on a north border. The result has been far from satisfactory on the latter site given a damp, chilly, sunless time after the insertion of the cuttings.

BEDDING OUT.—Our beds and borders have been gradually so filled up with hardy plants, that what is known as bedding out has been reduced to a minimum, and the work is nearly finished. In some beds of Violas the only work necessary has been the dotting in of an occasional large plant of *Fuchsia*, or where other things have been mixed with them for a spring show, as, for instance, *Saxifraga umbrosa*, and a very charming bed this makes associated with a dark purple *Viola*: the *Saxifraga* is removed to be replaced by something else that will be likely to make a nice combination for the summer months. *Dactylis glomerata* is one of the specially good things. One or two hardy, or hardy and half-hardy combinations that were a success last year are similarly planted for the present season. One is clumps of the variegated *Digraphis* filled in with crimson *Antirrhinum*. This, it may be noted, is a mixture eminently suitable for poor soil beds, the grass under such conditions preserving its variegation in a pronounced form well through the season, and the *Antirrhinum* flowering with great profusion. Another rather pleasing contrast will be found in *Spirea palmata alba* on a groundwork of *Petunia compacta*, a dwarf striped variety that wants hardly any pegging, and that makes an admirable carpet for things of taller growth, as the white *Spirea*. *Aproros* of this family, what a difference there is in the habit of growth of different varieties. Some form large clumps quickly; others, as *astilboides*, are a long time making a clump of any size even on a cool, partially shaded border. *Petunias* rank among the best of summer bedding plants of trailing habit, and besides the *nana compacta* strain I grew last year *Giant of California* and *Carter's Blue*, which were respectively decidedly satisfactory in the positions assigned them. The free-flowering *Tropaeolums*, those that give a plentiful supply of flower on comparatively scanty foliage, are also satisfactory and seem to be increasing in favour. A very nice bed on a large scale can be formed with blocks of the small white-flowered *Marguerite* filled in with the trailing *Ball of Fire Tropaeolum*. In yellows, *Mrs. Clibran* is a capital variety, its peculiar deep orange shade being, I think, almost unique in outdoor summer-flowering plants. Another hardy bed that will presently be hard to beat and that has indeed been gay for some time is planted with alternate blocks of *Gypsophila paniculata* and *Montbretias*, the latter on a carpet of *Phlox setacea*. It is, by the way, as well to examine the *Gypsophila* early in the season before growth commences, and, if necessary, to lift healthy crowns, divide, and replant to make up for losses. Many crowns have altogether disappeared this season. The flowers of the alpine *Phloxes* will soon be over, and if an increased stock is required, cuttings may soon be inserted. I generally put them in the frame that is made up for Pinks and Violas, and they get a little shade for a time after their insertion. Poor, bare slopes might with advantage be furnished with these *Phloxes*, as they always

give a nice green carpet, and truly in the flowering season they are veritable sheets of bloom.

Claremont.

E. BURRELL.

The common Bugle.—One of the prettiest things in my garden is a mass of the common Bugle (*Ajuga reptans*). Apparently self-sown, it came up two or three years ago in an odd corner, where it interfered with nothing, and spreading over the surface of the soil forms a mass of spikes of bright blue. It shows the bronze-tinged foliage peculiar to it, and which contrasts well with the colour of the blossoms. Some would probably be inclined to spurn it as a common weed, but it is pretty enough to rank among cultivated plants.—R. D.

Viola Blue Bell.—When at Syon Gardens, Brentford, a few days ago, I found Mr. Wythes was using this variety somewhat extensively as an edging to his summer flower beds. Mr. Wythes holds that for compactness of habit, freedom and continuity of bloom, and non-liability to mildew, it is the best of the Violas for this purpose. Seeing this variety, which originated as a chance seedling, was sent out in 1873, it may be regarded as one of the oldest in cultivation, and it can be found in many gardens. I have raised a goodly number of seedlings from it, but have never exactly reproduced the variety itself, though possibly others may have succeeded in doing so. A *Viola* that can hold its own for nearly a quarter of a century must possess good qualities in the face of the many hundreds of seedlings raised within the last twenty years.—R. D.

## GARDEN FLORA.

## PLATE 1016.

## CYCLAMEN PERSICUM.

(WITH A COLOURED PLATE OF C. SALMON QUEEN.\*)

Not in every instance does the real lover of horticulture follow in the footsteps of the ardent florist as regards the beautiful. The ideal standard of the latter is more frequently than not based upon lines that cannot be accepted from the point of true beauty. It is no small wonder, therefore, that a divergence of taste ensues. As an instance, no better example can be given than that of the show *Dahlia* as contrasted with the present-day forms of the *Cactus* varieties; the latter are infinitely more attractive than the former, whilst as regards choice for use in a cut state, those of the show type have no chance with those of the *Cactus* class. With respect to the present-day race of *Cyclamen persicum* there is not this division, the improved forms being in every sense superior to the older ones. These divide themselves into two classes, but in both instances the beautiful predominates over and above any of the hard and fast lines of the florist. It is not an easy matter to say which of the two sections is more to be admired—that designated the *giganteum*, or that known as the older form—as regards growth. Both are very free-flowering, the latter being on the whole the more compact in habit, whilst again the foliage of both is beautifully marked, that of the *giganteum* type being the more imposing.

The illustration affords an instance of the advance that has been made from point of colour, the name conveying at once the best description of this. When the writer first saw the plants that were exhibited by the Messrs. Sutton and Sons, of Reading, at one of the

\* Drawn for THE GARDEN in Messrs. Sutton's nursery at Reading by Miss Low, November 12, 1894. Lithographed and printed by Guillaume Severens.

earlier meetings of the R.H.S. this past spring, the impression was at once stamped upon the mind of its thoroughly distinct colour, and its other equally good properties of free-flowering, compact habit, and beautifully marked foliage. These alone form a trio of good qualities that it would be difficult to surpass. A further opportunity was afterwards afforded of inspecting the larger quantity as growing in one of the Cyclamen houses at Reading, when the first impressions were more than confirmed. This particular shade of colour was seen to better advantage under the clearer atmosphere of Reading as contrasted with that which pervades the Drill Hall on most occasions. One other of its good qualities should be noted, viz., that of producing its flowers well above the foliage.

Salmon Queen being now placed in commerce, is within the reach of all lovers of these charming spring flowers, amongst which it will take a foremost place, being quite unique in its good properties. Other Cyclamens in great variety are grown at Reading for seed alone, the stock of which in each instance is as pure as

safely added ere they ceased to flower. This fact of extended blooming, combined with the large blossoms produced upon stout footstalks, points to this race as the very finest for supplying cut flowers. Giant Crimson, White, Cherry Red, Rose, Purple, and Crimson and White are all most distinct in their colours, it being a difficult matter to say which is the finest of these.

#### THE CULTURE

pursued at Reading does not materially differ from that in usual practice. The seed is sown in November, the pans being kept in a temperature of from 55° to 60°. Earlier sowing is advised if less heat is given. Pricking off takes place in March, when for a short time the temperature ranges as high as 76° to 80°, the spent hotbeds in frames being the next move, no rest being given. Note, however, should be made of the all-important fact that the seed is sown with the greatest possible care, each seed being treated separately at a distance apart of from 1½ inches to 2 inches. This is an item of culture of which it is difficult to make too much; it prevents the check—slight though it may be

out in a cool, shady place, to grow into size by the autumn, planting deeply and treading them firmly into the soil. If neglected during summer, the plants soon suffer. How seldom one sees the variegated-leaved variety *aucuba-folia*, one of the most charming and effective of early spring-flowering plants. It is an interesting process to raise seedlings. I have a line raised from seed of the double white, nearly all fully double, and some bearing finely-formed blossoms, smaller than those of the ordinary cultivated type.—R. D.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**EARLY FIGS IN POTS.**—Fruit of pot Figs forced early will now be getting smaller, and the plants if not too large and rooted into the plunging material will do much better if removed to a cooler house. Some varieties fruit much later than others, and may now be in full bearing. These, of course, will require to be kept growing freely and the shoots stopped for the production of later fruits. For early forcing in pots the St. John's and Pingo de Mel are far ahead of older varieties and require special treatment, such as early ripening of the wood, repotting during the resting period, and standing in the open in a sunny position during the summer months. Such well-known kinds as Brown Turkey, Negro Largo, and Bourjasotte Grise are now perfecting their second crop, and will make much later growth than the white-fleshed varieties named above. Ample supplies of food and moisture should be given, and the new strong wood kept hard stopped to induce a short-jointed growth. The plants of all varieties in pots which have been forced should be mulched at this date. In the case of the earliest kinds it is well to either plunge in the border or in larger pots when the plants are being hardened off, as they soon suffer if the sun shines directly on the pots. There should be no lack of water and food also in the way of liquid manure during the summer months, it being advisable to retain the old foliage as long as possible. Plants infested with scale should be cleansed after the fruits are gathered, and care taken to preserve the leaves. If not badly attacked, thorough syringing and a fine brush will remove the pest. Large old trees that have been many years in brick borders or restricted areas should get unlimited supplies of food if swelling a second crop, and be treated as advised for smaller pot plants. It is surprising what heavy crops these plants produce annually with ample surface dressings and rich food. Pot plants will bear three crops if required to do so, but I do not advise this, as it weakens the early crop for next season. Those who intend to force hard next year would do well to get the wood well matured after the second crop, removing any fruits which show, and if the trees are movable, removing later on into the open.

**PLANTED-OUT SUCCESSION FIGS.**—These will now be finishing the first crop in many houses, and require care to keep the smaller fruits moving rapidly whilst the first crop is finishing. It is well to go over the trees early in the day and gather any ripe fruits, as syringing soon spoils them. Should there be any doubt as to ripeness, it is well to omit syringing and allow the fruits to hang a little longer. Stopping and feeding will be the chief points of culture, and if the trees have filled their allotted space and cannot be extended, the treatment may be varied. Instead of laying in the wood the large shoots may be pinched in the same way as those of pot trees, and thus abundance of fruiting spurs be obtained, removing useless spray or weak wood. Should the trees be old with any barren or naked branches, it is well to lay in a reserve of young wood, cutting out the old naked wood when the crop is cleared. Select the best formed shoots and stop hard back the lateral growths not required for extension, laying in the latter their full length. At this

A white Cyclamen.

it is possible for distinct strains to be. Of these, particular note should be made of Vulcan, which has flowers of the deepest crimson, a colour that looks very rich under artificial light. In decided contrast to the foregoing that of Butterfly should be noted; this is quite a gem among the white forms, having no rival from the points of beauty and utility; the growth is very dwarf, the foliage being only of medium size, in addition to which the flower-stems are so sturdy as to require no staking whatever. The petals of this particular variety are quite notable by their breadth, so much so as to be quite overlapping. Purple Queen is a selection from Salmon Queen, differing only in point of colour, thus possessing a better constitution than most varieties of this shade. Roseum album greatly resembles Butterfly, with the addition of a crimson base.

The giant forms are kept by themselves. An intensely vigorous growth with large flowers in the greatest profusion characterises this section. Another feature, and that an all-important one, is the length of time these remain in perfection; when seen the plants had been in bloom for three months, and another three could be

—that is occasioned by an early pricking off into pans or boxes, this being entirely avoided. When done, however, each little corm is lifted with sufficient soil and roots to keep the growth progressing, no resting period being given until the seed is harvested; after which a selection is made of the most promising corms for the second year, more to make a display and to demonstrate what may be done than anything else. Large pots are studiously avoided, the second year plants being flowered in 6-inch and 7-inch pots, those of the first year in the next smaller size. SOUTHERN.

**Double Daisies.**—These pretty spring flowering plants appear to be somewhat neglected by gardeners, though they can be made of great service in the spring garden. There are the dark and pale crimsons, several shades of pink and forms of the double white, all plants of a hardy character, easily propagated, but requiring only a little attention. There should be two periods of planting for the double Daisy—in October, when they are put out in the spring beds, and at the end of May or early in June, when they are taken up to make room for the summer occupants. Then the plants should be divided and planted

season seale makes its appearance on old trees, and should be taken in hand as soon as it shows itself, as if allowed to spread to this year's growth it is difficult to eradicate. When the pest shows on the old wood it is readily removed with a soft brush dipped in paraffin solution or methylated spirits, and syringing freely daily will keep it down. The horders will now need a rich fertiliser. Young trees are much benefited by a top dressing of bone meal if fruiting freely. Owing to a short spell of hot weather the foliage got browned in exposed houses, and will soon get red spider if not syringed freely. The colour may readily be restored and the trees kept clean by syringing with clear soot water. Varieties such as Negro Largo with gross wood and too much root-run are at times barren of fruit, and I have taken strong measures to get a second crop by cutting a trench at some distance from the trees and filling in with concrete. The trees make much shorter joints, but of course require much moisture, keeping the shoots thin. By this means a good crop of late fruits is secured.

**LATE FIGS.**—Figs grown without heat will this season be invaluable, as the majority of trees on open walls have been much injured by the severe frost and will only fruit sparingly. The trees in eases or late houses show a great quantity of fruit, and as they only produce one crop the fruits should be regulated accordingly, removing any badly placed ones and thinning where too thick. As the fruits are often at the upper portion of the trees they may be left much thicker there, to check the upward growth of the trees if much extension be not required. The best mode of culture for late trees is by extension. There is never any difficulty in having abundance of clean bearing wood on these trees under glass, and it is well to remove all naked or badly-placed branches. Young trees required to cover a good space should not be allowed to carry fruit on the branches left for extension.

**PREPARING YOUNG FIG TREES.**—I have found it well to grow a few young trees in pots yearly to take the place of old ones which are too large. As good fruiting plants may be grown in two seasons it is well to prepare a few yearly for this purpose. Plants struck very early in the year will now be in condition to be shifted into 7-inch or 8-inch pots, and should be potted firmly in strong loam, to which have been added bone meal and some old mortar rubble. Plants struck last season may now be shifted into the fruiting pots, those 10 inches or 12 inches in diameter being suitable. In thinning the growths it is well to pay more attention to those varieties which are straggling growers, keeping them to one stem and getting a symmetrical head. Grow as near the light as possible in a warm house, but do not force much, relying chiefly upon sun heat during the day.

**EARLY MELONS.**—The plants on which nearly ripe fruit is hanging should be kept moderately dry, there should be no falling off as regards heat, and more air will be necessary to obtain good flavour. On bright sunny days a constant current of air during the day with a free circulation of heat through the pipes will give ripening fruits the rich aroma so much liked. In well-heated houses it is advisable to leave air on all night when the fruit is colouring. Watering plants far advanced will now require more than ordinary care, as in mixed houses all cannot be treated alike, some varieties ripening much earlier than others. Many fruits are ruined as regards flavour by being cut before the stalk cracks and ripened on shelves. I am aware one is often obliged to do so to forward Melons, but I have never tasted a good fruit cut prematurely. The fruits colour well, but sadly lack the flavour of those ripened on the plants. The weather of late has been most trying to the Melon crop, as after a spell of brilliant sunshine we have had dull cold weather, just the reverse required, and bringing canker and cracking in its train. The plants will need more than ordinary care, and should the stems crack it is well to arrest decay as soon as noticed, using finely powdered charcoal and quicklime freely where affected. Plants swelling their

fruits will need liberal supplies of food in the way of liquid manure, or quick-acting fertilisers given at alternate waterings.

**MELONS IN FRAMES.**—Many are obliged to grow Melons in frames, and as there is no better time to plant than now, sturdy clean plants should be selected for the purpose. Very good Melons may be grown in pits or frames just cleared of other plants. The bed should be well rammed so as to have a firm base, and a small quantity of prepared soil placed in mounds for the plants, planting out when the soil is warmed through. I have found it a good plan to grow the plants on a trellis. The plants supported in this way are freer from canker, get more light, and are readily attended to. The fruits, too, are much superior to those resting on the soil. A good trellis may soon be erected with Bamboo canes, fixing these 12 inches clear of the glass, and training two plants one each way in a light. G. WYTHES.

#### KITCHEN GARDEN.

**PLANTING OUT LEEKS.**—These, where required early in the autumn, have to be sown in heat in February, and if the plants have been duly hardened off in frames they will now be ready for planting out. The best Leeks are obtained from the trench system, as not only can earthing up be better accomplished, but feeding also, the trench holding the liquid manure so that the roots get the whole benefit of it. Take out trenches similar to those prepared for Celery, but somewhat shallower, digging into the bottom a good allowance of rotten manure. Pig manure is the best for Leeks, and after firming it somewhat and watering if necessary, plant the following day. Separate the young plants with great care, as the tender, succulent roots are easily damaged. Make holes from 9 inches to 1 foot, plant deeply, allowing the tops (which should be slightly shortened) to descend a little below the ground level. Cover the roots and finally water again with a fine rose. The plants will then take care of themselves until well above the ground again and in active growth, when good supplies of liquid may be given, or, failing this, a good fertiliser sprinkled in the trench during showery weather, or if dry, watered home. Leeks in open-air beds must have every encouragement to grow ahead. If the plot intended for this main crop is not yet ready, lose no time in preparing it. When planting takes place it is a good plan, where there is a great demand for this vegetable, to select the smallest roots for planting on a well-prepared plot rather thickly and in the ordinary manner. These will be found very useful for soups and other odd purposes during winter. In planting take care that no soil is allowed to drop into the hearts of the plants.

**ROOTS.**—In some districts which have been favoured with genial rains, thinning in this department will not only have become general, but comparatively easy. Even where no rain has fallen the work must be commenced, or crowding and consequent weakness must follow. Onions may be raised with the aid of a pointed stick, and thus prevented from snapping asunder beneath the ground. On very hard, baked soils watering with a rose the day previous to thinning is a capital plan. Where the dreaded Onion maggot is likely to be troublesome, thin at first in moderation, as often this pest will attack the bulbs when of considerable size, and if thinned very freely at the start the crop by their attacks is greatly reduced. Bear in mind the importance of using the Dutch hoe and of frequent sprinklings of soot and guano in showery weather. The final thinnings of Beet may now be made, except in the case of the latest sowings, and where, as is sometimes the case, blinks have occurred in the rows, they may be made up in ten days' time by transplanting. Leave one row thicker at present from which to secure those for transplanting; raise them carefully by the aid of a pointed stick or label, and plant with a dibber, or if time can be spared, draw out a trench, moisten it well, and plant the next day, firming the soil well with the feet. I have often practised transplanting Beet, and found it answer well.

**SMALL SEEDS.**—These are often neglected in dry soils after sowing; consequently they fail to germinate properly, the seedsman being blamed for poor results. It is a good plan when the seed bed is in a sunny position to cover it with mats or bags, first watering it thoroughly, which will suffice until the seeds come through the ground, when the coverings must be removed. Watering several times weekly will be necessary, and early thinning when the first pair of rough leaves have formed. The neglect of these details is often the forerunner of bolting in the autumn and of inferior crops generally. After this date thin sowings of Lettuces and all small-seeded subjects are best, as there is not much fear of failure provided a reasonable amount of care is taken.

**FRENCH BEANS.**—Some time ago I advised all who had the convenience to sow a good batch of Canadian Wonder in 9-inch or 10-inch pots, placing the same in any light position, not necessarily on shelves, in a cool house, using good rich material and feeding liberally as soon as growth was a few inches high. Good tall, stout branches will also be needed to support growth, and as soon as the Beans come into bloom, apply a good mulch of farmyard manure to the surface of the pots. This treatment, coupled with a constant supply of fresh air, will produce astonishing crops of this Bean, and, provided the foliage is kept free from spider by rigorous syringings twice daily, it is surprising how long they will continue in a bearing state. I have for years grown a good batch of Canadian Wonder in pots as described, and find them most serviceable, coming in just before the frame-planted ones, which are treated quite coolly. These latter may now be also mulched, as growth will be advanced, but the nights having turned much cooler, protection must still be given, nothing being so detrimental to the well-being of French Beans as cold, dry winds. Where those have been brought on in small pots and planted on warm borders, the screens of Yew or Spruce boughs must not yet be removed. Where Scarlet Runners sown in the open are now through the surface, the same method of protection must be adopted. Thinning must also be carried out where too thick. To those that were transplanted and have grown 6 inches high, a little soil may be drawn. A free dusting of lime and soot or wood ashes should be given at the same time. Staking may also be done before there is any fear of the Beans falling about, but where staked too early the deficiency of light causes a weakly growth. Some place a row of sticks on each side of the line, but I do not care for the plan, preferring a single row of very tall ones, so as to allow the sun and light to play on all parts of the foliage and bloom-trusses. After the uprights have been inserted in the soil, cross rails must be placed horizontally along them, to which each must be secured.

J. CRAWFORD.

#### ORCHIDS.

##### ORCHIDS AT MR. WM. BULL'S.

ORCHIDS are manifestly so much more popular than they were a few years ago, that it is not surprising to find such an exhibition as that in Mr. Bull's nursery in the King's Road, Chelsea, visited by thousands during the summer months. For several years past Mr. Bull has shown by a superb display of Orchids how charming and valuable the flower in its many forms is for decoration, especially as plants arranged with Ferns and Palms. This year visitors will find a more beautiful show than has yet taken place. The large house with its glass mirrors at the ends reflecting the thousands of flowers never looked more brilliant, Cattleyas and *Laelia purpurata* in particular creating a splendid colour picture, whilst in another house 400 spikes of *Odontoglossums* can

be seen either in full beauty or approaching that stage.

The arrangement of the Orchids is delightful. One sees careful contrasts of colour, and how greatly species differ from each other in form and shade. A mass of *Miltonia vexillaria* arrests attention at the entrance, this Orchid varying greatly. On the one hand we get a variety named *albescens*, the flower of immense size and almost pure white, whilst hard by is *rubra superba*, a neat flower, small, but rich rose in colour, quite the opposite of the other in size and colour. A variety of *M. Roezli* named *splendens* is very handsome, the flower much larger than usual and white, with a dark blotch at the base of the segments.

One of the chief features of the exhibition this year is *Laelia purpurata*. The splendid spikes of finely-coloured varieties stand out conspicuously from the mass of other Orchids. They are superb for strength and beauty of colouring, some receiving distinctive names such as they well deserve. *Atro-purpurea* is one of the most beautiful, the sepals and petals white, with a deep crimson-purple lip in strong contrast. *Fulgens* is very different from this; it has quite rosy purple sepals and petals, with a splendidly coloured lip, deep yellow in the throat. *Picta* has white segments, the lip crimson-purple in the upper part, white in front, set off by a lemon-coloured throat—a very charming and distinct kind. *Refulgens* was exceptionally fine, the lip being large, well shaped and of a self crimson-purple. *Bella* is another handsome variety, with white sepals and petals and a pretty rose-coloured lip; whilst in a form called *marginata* we get a thin white margin to a lip remarkable for its intense colour, the sepals and petals of a rose-purple shade. *Victoria* is a lovely kind, with pure white sepals and petals and a deep crimson-purple lip in very rich contrast. Many others we could mention, but our aim is not to create a string of names, rather to indicate a few of the gems in this collection.

The Orchid lover will note also another splendid feature—*Cattleya Mossiæ*, *C. Mendeli* and their respective varieties. *C. Mossiæ* was distributed in groups on the stages, thus breaking up the arrangement satisfactorily, one getting at the same time a rich mass of colour. *Lawrenceana* we made note of as a fine variety, the segments very broad and the lip with a fine white edge. Nor must we forget such varieties of *C. Mendeli* as *Empress*, rich in colour and beautiful in form, or *Rex*, with white sepals and petals and purple-rose lip. A lovely Orchid is *C. Schroderæ aurantiaca*, one of the most sweetly scented of all Orchids and charming in colour—delicate lilac, set off with a rich orange throat.

Suspended in baskets is the pendent spiked *Odontoglossum citrosum*, a species not difficult to grow, and represented by several forms. *Punctatum*, as its name suggests, is spotted, the sepals and petals cream colour spotted with lilac, the lip lilac. *Rubrum* has quite rose-coloured flowers, and in other forms colour differences exist which increase the charm of this beautiful *Odontoglot*. The clear self-yellow *Oncidium concolor*, its pendent spikes giving a rich gleam of colour overhead, and the brilliant *O. Rogersi* contribute masses of yellow to the display very different to the quiet-toned *O. pulchellum*. The *Masdevallias* are noteworthy, and one of the brightest is *M. Harryana Comet*, the flower well shaped and bright crimson in colour. *Regalis* is deep crimson and one of the handsomest of all the forms of this type.

A few other things we singled out of this choice display were as follows: *Cypripedium Mastersianum*, *C. niveum majus*, *C. grande*,

and *C. Curtisi giganteum*, all bearing remarkably fine flowers, particularly the last mentioned; also *C. barbatum*, a well-known Lady's Slipper, and which is largely represented. *Laelia elegans Schilleriana* is very pretty, the flowers deep crimson, lemon coloured in the throat. *Cymbidium Lowianum concolor* is a good variety, distinct from the well-known species in having flowers without any crimson colouring. *Trichopilia lepida* was in fine flower, also the rich brown-coloured *Phaius bicolor* and *Scuticaria Hadweni*, the flowers deep chestnut-brown, barred with yellow, the lip white and light brown. Nor must we omit to mention *Phalaenopsis Schilleriana*, *P. Stuartiana*, and the beautiful *P. Luddemanniana*, represented by a very bright and handsome form.

The *Odontoglossum* house, to which we have already referred, is a picture of blossom. The hundreds of racemes are exceedingly graceful, the majority of the plants being those of *O. crispum* (*Alexandri*) and its varieties. *O. Pescatorei*, *O. cirrhosum*, *O. Halli illustre*, deep brown and yellow, the pretty *O. radiatum*, *O. polyanthum*, *O. ornatum*, and *O. Andersonianum* were also represented in this feast of *Odontoglots*.

**Masdevallia nycterina.**—This attracted much attention at the Temple show recently, a very large specimen being placed in a conspicuous position at the corner of Baron Schroder's exhibit. The plant was growing in a large basket, and was well furnished with a quantity of erect, oblong, lanceolate leaves and a considerable number of flowers, which bang around the basket on short stems. The flowers, borne singly on the peduncle, are triangular in shape, the sepals terminating in slender tails about 2 inches long. These are of a brownish purple and yellow colour, somewhat hairy and spotted with black. The species is a native of New Grenada, where it grows at an altitude of between 5000 feet and 6000 feet, and has been in cultivation about twenty-five years. It was first known as *M. Chimera*, but was found by the late Professor Reichenbach to be quite distinct from that species and was named by him as above.—W. H. G.

**Epidendrum Stamfordianum.**—This is an exceedingly pretty species, especially when seen so well flowered as was the fine specimen shown at the Temple by Mr. White, gardener to Sir Trevor Lawrence, Bart. This plant carried upwards of a dozen and a half fine branched spikes, each supporting numerous blooms. These individually measure about 1½ inches across, the sepals and petals yellow, spotted with red. The lip is flat, white, with a bright rose spot on the crest and at the apex of the column, forming a very pretty combination. This species, although an old inhabitant of our gardens, is by no means often seen in bloom. It was originally discovered in 1837 in Guatemala by Mr. Ure-Skinner, growing on the shores of Lake Isabel. Of this species there is a very pretty variety named *E. Stamfordianum Wallacei*, which produces a somewhat shorter spike, the sepals and petals being more densely spotted with reddish purple, the creamy white lip also spotted with the same colour.—W.

**Cattleya Mossiæ.**—This very showy *Cattleya* occupied a foremost rank amongst the numerous exhibits at the recent Temple show. It is one of the most variable kinds in the genus as regards the colour of the lip, scarcely two plants being exactly alike, although each shows its characteristic markings. I am in receipt of some fine blooms from Mr. Joseph Broome, of Sunny Hill, Llandudno. Number 3 is the best formed bloom and of rich colour, the sepals and petals of a deep rosy lilac, the finely fringed lip velvety purple, and having a distinct white margin. Number 4 is a paler flower, but much larger, measuring 9 inches across the sepals, which are broad and nicely undulated; the lip large and

crisped, with a yellow throat; the ground colour very light, but prettily veined with rosy purple. The flower with no label is of good form, but smaller, having dark rose sepals and petals, with a well expanded lip, measuring 2½ inches across, nearly white, with a few pale rosy veins in the centre. It appears to me that unless there is something very distinct in the flowers of this species it is impossible to give them varietal names. There are, however, a few varieties which are very distinct, such as *C. Mossiæ Reineckiana*, a beautiful plant of which was shown at the above mentioned exhibition by Messrs. Low and Co., of Clapton. In this kind the flowers are pure white with the usual yellow disc, and beautifully veined down the centre of the lip with purplish carmine. Another chaste and lovely kind is the pure white variety named *C. Mossiæ Wageneriana*, which was also exhibited in several of the best groups. Even these plants showed great variability in the size and form of the flowers, some having scarcely any yellow in the throat, while in one plant shown by Baron Schroder the flowers were of massive size, the large lip heavily shaded down each side with golden yellow.—G.

**Masdevallia muscosa.**—This was named by Professor Reichenbach in 1875 from dried specimens brought home by Mr. Shuttleworth, who found it growing in San Domingo, in the province of Tolima, New Grenada. It is a dwarf-growing species with deep green leathery leaves, purplish beneath and about 2 inches high. The flowers are about three-quarters of an inch in diameter, with narrow, triangular-formed, pale yellow sepals, which are prolonged into tails about 1 inch in length. The lip, which is the most interesting part, is also yellow, edged in front with maroon-purple.—W.

#### MEXICAN LAELIAS.

The *Laelias* from Mexico form a very beautiful and distinct group, most of which can be recognised by the pyriform shape of the pseudobulbs. These may be generally cultivated under the same treatment as that usually advised for *Cattleyas*. First amongst the Mexican *Laelias* must be mentioned the beautiful

*L. majalis*, which is considered one of the most difficult of all Orchids to flower. This to a certain extent is quite true. In its native habitat it appears to be very free-flowering, and is known as *Mayflower*, thus indicating its natural time of blooming. At the recent exhibition in the Temple Gardens I noticed this species in bloom in several collections. The blooms of *L. majalis* are not only exceedingly beautiful, but they are also very large, measuring about 7 inches in diameter, and, considering the size of the bulbs, this is truly remarkable. This *Laelia* is an old inhabitant of our gardens, having been imported many years ago. The flowers are usually produced singly upon a peduncle, but in well-grown examples I have sometimes seen two blooms. The sepals and petals are large, the latter much broader than the former, and both of a delicate shade of pale rosy-lilac; the lip is lighter in colour, sometimes white, spotted with purple, and with a border of mauve. The plants should be well elevated above the rim of the pots or placed on blocks of wood, but they dislike being disturbed after they have become established. When, however, repotting becomes absolutely necessary it should be done with care, so as not to injure the roots. During the growing season water should be abundantly supplied, but when at rest very little is needed so long as the bulbs remain plump and healthy. The plants should be suspended near the roof and plenty of light and air admitted, with a nice moist atmosphere, very little shading being required even when the sun is very powerful.

*LAELIA ANVERS* is another fine Mexican kind, and one that is at present grown in nearly every collection. It is a most useful plant during the dull winter months, the flowers ranging in colour from pure white to rich purple. This species and its varieties also flower much better after they

have been well exposed to the sun and the growths nicely ripened. It succeeds best upon a block of wood suspended close to the glass, and thus occupies but little space. The white-flowered kinds, which are natives of the Pacific coast, require a little more warmth to grow them to perfection. The flowers of

*LELIA FURFURACEA* are also of a very lovely shade of pale rosy-purple, these individually measuring between 4 inches and 5 inches in diameter, and carried several together upon an erect peduncle. This kind was introduced about sixty years ago, and is always found growing at considerable elevations, thus showing that it requires cool treatment under cultivation.

*LELIA ALBA*, although it has smaller flowers, is a very charming kind. The blooms, white, sometimes flushed with rose, the lip having three bright yellow lines on the disc, are each about 2 inches in diameter, and carried from four to eight on long slender spikes about 18 inches in length. Of this kind there are also many varieties, the flowers of some being of a deep colour, those of others ranging from pure white to sulphur-yellow. This plant is also found at an altitude of from 7000 feet to 8000 feet, and under cultivation does best when placed upon a block and suspended near the glass.

*LELIA RUBESCENS* has flowers of similar size to those of the preceding, and is sparingly spread over Mexico and Guatemala, the blooms white or shaded rosy-lilac, with a large blotch of rich maroon at the base of the lip. It has been imported but sparingly compared with the others above mentioned, but it is a very desirable kind. It is also known as *L. peduncularis*.

*LELIA AUTUMNALIS* is also a very popular kind, which flowers in the autumn and winter months. This plant produces a spike of from five to nine blooms, each about 4 inches in diameter and of a bright rosy-purple, becoming lighter at the base of each segment. G.

#### EPIDENDRUM BICORNUTUM.

This is certainly the most beautiful *Epidendrum* in cultivation, and a remarkable Orchid in many respects. It has not been found to live long, the pseudo-bulbs usually being not so fine after a few years' growth as when first imported. Nevertheless while it lasts its distinct character always ensures it a host of admirers, and if a little care is bestowed upon it, one may reasonably expect a fair return in the way of flowers for five or six years at least. Possibly the plants while they last are happier on blocks very lightly dressed with *Sphagnum* than in any other description of compost, but as noted recently when speaking of *Phalenopsis*, even the most enduring of wood will not last long in the moist heat of a tropical Orchid house. The next best position for this Orchid is, I am confident, a deep pot filled nearly to the rim with potsherds, and a layer of living *Sphagnum* over this, the plants being placed in the hottest and most humid house at command. Newly-imported plants soon push roots in all directions among the rocks, taking hold of the sides of the pots and revelling in the moisture afforded by the superficial layer of Moss without being hampered in any way by closeness of material. A little of the best fibrous peat would no doubt cause a stronger growth for the first year or two, but it would probably be at the expense of the future health of the plant, as the very best fibre becomes soddened in course of time from the continuous watering. While growing freely the species in question is almost aquatic in its needs, constant damping and syringing overhead being necessary to keep thrips in check and to maintain growth. The Moss grows rapidly, often reaching several inches up the stems, keeping them moist at the base and tending to the full development of the hollow fusiform pseudo-bulbs. During winter the greater portion of this must be removed, as it would hold too much moisture about the plants. The plants should have the lightest position available during the winter, and while re-

quiring much less water than during the growing season, must not be actually dried either in the atmosphere or at the roots, and the temperature must never go below 60°, excepting on the coldest nights, when it is better to allow a slight drop than to give too much fire-heat. *E. bicornutum* is ascribed to *Diaerium* by Bentham, but is more generally known by the former name. Its flowers are produced on terminal scapes in spring, from eight to twelve being the usual number borne on each. The individual blossoms are frequently 2 inches in diameter, of a pure ivory white, except for a few crimson dots about the labellum. This has two rather prominent horns, from which the species takes its name. It is found growing naturally on bare rocks and tree trunks in Trinidad and various other parts of the West Indies, and was introduced in 1834. The present is its blooming season, and the flowers last in good condition from a month to six weeks. R.

#### ARRANGING CUT FLOWERS.

AFTER flowers are cut and brought into the house their beauty is often marred, and the

this to be considered in gardens of limited extent. Many of us would be greatly relieved if those who arrange cut flowers (which at some seasons of the year have been obtained at a considerable amount of labour and anxiety) would endeavour to produce a maximum effect with a minimum of material. In many gardens throughout the country there are far more flowers grown for cutting than would be really required if due economy were practised in arranging them. The growth of flowers for the supply of families during the London season is a serious matter to the gardener, who would be only too thankful if they could be made to go farther than they now do, so that he might have more room and time to devote to other subjects. This object could be easily attained in the majority of cases if those who arrange the flowers did but study the art of grouping them, selecting those which blend harmoniously together, both in form and colour, using just sufficient to give an effect and natural beauty to the whole. Not only would the flowers used last much longer, but they would also give greater satisfaction.

*Iceland Poppies in a bowl.*

charming effect which they would otherwise have produced is utterly spoilt through bad arrangement. More frequently than not the idea of most people who arrange flowers seems to be to stuff as many as they can into any given receptacle, thereby thinking to show them off to the best advantage. What a mistake they make! and that at the sacrifice of both colour and form. Again, where several vases have to be filled, how often do we find one arrangement a counterpart of the rest—a piece of this and a bit of that may be seen in each vase. These are a few of the many instances where the beauty to be seen in flowers is deteriorated through the want of due amount of consideration on the part of those who have the arrangement of them. At the present time, when cut flowers are so much in request and so varied the objects to which they are applied, it is highly essential to economise them to the utmost; especially ought

When cutting flowers, the best plan is to fix upon what is intended to be used in each given receptacle, collecting only sufficient of each kind for the purpose, and avoiding a repetition of the same arrangement from time to time as much as the supply will admit of doing. By this means the flowers can be greatly economised, leaving, in many instances, a better display in the garden during the summer and in the houses throughout the winter months. The prizes offered at various horticultural exhibitions throughout the country have no doubt aided in a great measure to bring about a better state of things in the arranging of cut flowers. Lessons such as those showing the evil results and the low position in the prize list of those exhibitors who still adhere to the antiquated system of crowding flowers together for producing effect in floral decorations may often be learnt on such occasions by all of us. Much,

however, remains still to be done. The annexed engraving shows a well-arranged bowl of Poppies.

## KITCHEN GARDEN.

### DWARF OR FRENCH BEANS.

In looking through seedsmen's catalogues of the present day it is surprising how many of the old favourites have dropped out. A few seasons ago I made a trial of various kinds to test earliness, and found the newer kinds superior. Of course, in a private garden it is impossible to grow a large number of dwarf Beans, so that only a limited selection of sorts can be made, but I have had opportunities of seeing large breadths at Chiswick, and think we have improved the qualities of this vegetable of late years, as the pods are larger, more succulent, and less stringy. This is a great gain, as many persons object to dwarf Beans after the runner Beans are plentiful, on account of their so soon getting old and flavourless. This to a great extent is the fault of the cultivator crowding the plants and not supplying food and moisture. In a note on the value of French Beans mention must be made of the new climbing variety. I consider it a valuable addition, as when the weight of crop and the space occupied are taken into consideration it is one of the most profitable Beans grown. All who are interested in vegetable culture will welcome this variety. I feel sure it will hold its own and become a standard kind. The value of dwarf kidney Beans is their free cropping and earliness. They are not coarse, like some of the newer runner varieties, which, though much larger, are less prolific than some of the older types. To get tender pods, abundance of food and moisture and plenty of room should be given.

Few crops pay better than early dwarf Beans, and those who have light sandy soil may get much earlier crops than those who have a heavy clay to deal with. I do not advise too early sowing in unsuitable soils; on the other hand, it well repays the cultivator to make his land suitable, as few crops are more appreciated than early Beans. I have in previous notes pointed out the value of starting these dwarf Beans in heat or in cold frames, and when a few inches high planting them out on a sheltered border, with protection for a time. Treated thus, few vegetables give a better return, as the pods are produced at a season they are in great demand, and the plants will bear for months if well watered, grown thinly and fed freely.

As the season for early Beans is now at hand, a few words as to culture may not be out of place. Requiring early vegetables in quantity and having an unsuitable soil, I lost no time in getting many loads of road scrapings, burning every bit of garden refuse and carting in any quantity of old mortar rubble. These compounds mixed with old leaf soil made just the material for tender root crops, or those which required quick drainage whilst the seed was germinating, many early Beans being lost by too much moisture during that period in clayey soils. Many advise sowing thickly, but it is a great evil, as the fight for existence is so severe, that the crop is poor from the start and soon over. It may be said there are such losses that thick sowing is a necessity, but such is not the case, as a few gappy rows can soon be made good by transplanting. I have found that by making three sowings, one under glass for planting out early in May, another at this season, and another a month or six weeks later, there is no lack of pods for a long season or till

cut down by frost. I am aware the two main crop sowings require much food, but if there is no lack of manure and each plant given room to develop, there will be no trouble with the crop if the pods are regularly gathered. I have gathered three crops from Canadian Wonder planted out when hard forced. For early cropping few varieties are superior to Ne Plus Ultra sown early in May in good land. It is a very fine type of dwarf Bean, of compact growth, and enormously productive. It is equally good for forcing very early, and the pods are of delicate flavour. The earliest Bean I have grown is Mohawk or Six Weeks, but it does not yield so long as some varieties. I consider this best for early outdoor crops. The well-known Syon House is always reliable and valuable for early crops. For summer or main crops, such varieties as the Negro Long pod and Canadian Wonder are the best, but they require more space, especially the latter. I prefer to give Canadian Wonder 3 feet between the rows and each plant quite 10 inches apart, as this variety if crowded is soon over. Given space and liquid manure, Canadian Wonder is a profitable variety. Such varieties as Ne Plus Ultra and Syon House require less space. Those who depend upon these Beans for summer crops should grow them in deeper drills than those for the earlier sowings, and during growth the soil between the rows should be mulched with short manure to retain moisture. This saves the water-pot, and if the plants during hot weather can be given a damping overhead in the evenings there is no lack of pods of the best quality, while freedom from red spider which soon attacks crowded plants is ensured.

G. WYTHES.

**Too many sorts of Potatoes.**—I have recently planted no less than seventy-three distinct, or at least so-called distinct, varieties. That, of course, seems to be far too many. But then, as these plantings have been made in very diverse soils and various parts of the county, and as in no case does the total number of varieties in one place exceed twenty-four, the quantity after all will not seem to be excessive. Most of the well-known ones have been included, and very many others hardly known in the county. The object of the various trials is to enable local residents interested in Potatoes to see whether there are in commerce sorts not known to them, but which may be better adapted for their soils or purposes than are those at present generally grown, and that should prove useful in the respective localities. Possibly out of the whole collection some twenty or so may be found exceptionally good.—A. D.

**Winter Lettuces.**—I find the two best Lettuces for standing the winter are Dickson's Imperial Brown Cos and Black-seeded Bath Cos. I made a small sowing of the above varieties on September 29, 1894, and transplanted when large enough to handle in rows 12 inches apart, and 9 inches from plant to plant, on a west border shaded by a wall 9 feet high. I did not lose more than eight plants, the blanks caused being immediately filled out of the seed-bed. In the middle of April I tied up almost the half of them, which caused them to blanch beautifully. I have had a good supply of nice blanched crisp Lettuce, which will continue for another fortnight or longer, since the first week in May.—F. CLIPSTONE, *Dingley Gardens, Market Harborough.*

**Parsley.**—Where second sowings which are just through the ground show signs of being patchy, another sowing may now be made. Indeed, it is always well to be on the safe side with this uncertain crop, especially in hot, dry soils. Sometimes wireworm is very troublesome, taking the young plants wholesale when well advanced. At this date I would rather select a somewhat cool situation, as, for instance, in front of espalier

fruit trees, the shade from the trees suiting the crop well, and yet admitting enough light and sun to strengthen it. When sown keep the ground well moistened until the seed germinates; this watering is best given in the evening, as then it has a better chance of acting beneficially than when applied in the early part of the day. When evaporation is rapid a little rough litter spread over the seed row helps to preserve the moisture.—C. H. N.

**Tripoli Onions bolting.**—Comparatively few beds of autumn-sown Onions stood the severe weather of February, they being so soft and tender, owing to such a mild temperature previously. Those that have a few are now troubled with wholesale bolting, this being due to the many extremes from warm to cold and from wet to dry during the present spring. The only remedy is to go over the bed and pinch out all the flower-stems low down, and to give the necks a severe twist. This treatment will often induce the bulbs to swell out to a good size; these ought always to be used first. I have this season proved the value of Trebons for autumn sowing. The bulbs here stood the winter and spring better than those of the Tripoli section, and are now growing rapidly. The finest white form of Tripoli, and one which I always grow, is Leviathan. Under good cultivation this Onion will attain to enormous dimensions, and the flavour is mild. Now is the time when winter Onions should be doing their chief work in swelling; therefore, should rain be scarce, artificial waterings must be supplied, first giving the beds a good sprinkling of a quick-acting fertiliser mixed with a little soot.—C.

## STOVE AND GREENHOUSE.

### PELARGONIUMS AT LEWISHAM.

THE Ryecroft nursery, already famous for its Chrysanthemums, will soon be noted for other flowers to which Mr. Jones has now turned his attention. Judging from the magnificent display of Pelargoniums we saw there recently, his efforts in this latter direction have met with some success, as he is now distributing several new kinds of great merit, whilst the high quality of his collection, the good culture shown, and the profuse display of bloom entitle him to a place among the most successful growers in the London district. The show and decorative races of Pelargoniums have latterly declined in popularity, which is a pity, as one would think them altogether indispensable to those who want their greenhouses and conservatories gay with bright and seasonable flowers. Certainly no flowers of the present time can compare with, much more surpass, these Pelargoniums in their lavish display of varied colour, and all this beauty is of easy attainment by those who pursue the simple, but all-essential details of culture throughout the year. The commendable feature of these newer kinds is that they possess a free and robust constitution. When these Pelargoniums were popular show flowers owing to in-breeding to maintain high quality and show form, not a few varieties were raised that sadly lacked a robustness of habit and free growth. But setting aside the conventionalities that governed the shape and colour, and seeking the natural grace and expression of the flower in varied forms and hues, there is no reason why these Pelargoniums should not again be popular, and, judging from the varieties that Mr. Jones is now growing, it will be surprising if some of them do not become valuable market plants.

Of all the varieties that have come and gone we can recall nothing resembling or at all like the variety Mr. Jones has named Eucharis.

Its flowers are of the purest white, without a spot or shade of any other colour, and quite unique in shape and disposition on the truss. They are quite round in outline, almost flat, broad in the petal, and of large size. Each flower has a stem 2 inches in length, so that the individual blossoms can be gathered singly and are adapted for a variety of uses. The truss itself is flat, having only from three to six flowers, but they are freely produced upon the plant, and the habit of growth is all that can be desired. It is a charming variety, appropriately named. The centre of attraction in the house was a kind named Mrs. H. J. Jones. The flowers of even other fine kinds looked small in comparison, whilst its colour is soft and delightful. The immense flowers form a bold truss, and all the plants were finely bloomed. In colour it is pale flesh, shading to blush-white, with two small pencilled blotches of rich crimson on the upper petals. Mrs. H. J. Jones in colour and size of bloom does not appreciably differ from some of the older kinds, but it is a marvel of profuse bloom, and useful on that account. Its flowers are rosy red, with white eye and dark blotches. Mrs. W. Wright is a lovely kind that received an award of merit last year. It is strong in growth, profuse in bloom, its flowers when first open clear soft pink, shading to pale blush and having two small feathered crimson blotches. The flowers of May Queen are of a salmon-rose colour with white throat, the nearly black blotches almost covering the upper petals. Duke of York and Lady Duff are two fine varieties of the regal type, the former bright rosy crimson and of large size, the latter a clear red sport from the variety Duke of Fife. Miss Alice Love, flesh-pink, with large dark blotches, is pretty, also Duke of Portland, which is soft rose, with white throat and dark velvet-black blotches. Multiflora, rosy pink, with crimson stains, is as free-flowering as the name implies. A few of the other kinds that are specially noteworthy are Jubilee, clear pink, with maroon blotches; Rose Bard, rosy carmine, feathered with maroon, very free-flowering; Mrs. H. M. Stanley, blue-mauve, with dark blotches; and H. M. Stanley, rosy lake, upper petals crimson, with dark spots, habit free and a profuse bloomer.

Ivy-leaved varieties are favourites with Mr. Jones, and to these as well he has made several notable additions, especially in Rycroft Surprise, a sterling kind. Its growth is vigorous, the dense flower-trusses stand up well from the plant, the individual flowers of very large size and of a lovely salmon-pink colour. Beauty of Castle Hill, with soft pink flowers and a free, dwarf habit, should be a favourite kind, whilst Rycroft Scarlet is quite the best of that shade of colour. Liberty, light rosy magenta, very free blooming; Le Prophète, cerise-red, with large flowers in a neat truss; Lamartine, light orange-red; and Jersey Beauty, of a reddish purple shade and free habit, were all noteworthy. The zonal varieties are all well done, and although nothing new was in bloom at the time of our visit, we saw good batches of seedlings that will soon be in flower.

**Reidia glaucescens.**—This is the name under which the plant mentioned above is most commonly met with, though it is now regarded as a *Phyllanthus*, whose specific name is *pallidifolius*. It is a plant of easy culture and very graceful habit, the little glaucous leaves being arranged regularly along the branches, which are disposed almost horizontally, thus giving them the appearance of long pinnate leaves. The tiny drooping blossoms are borne in sufficient numbers to form quite a feature of the plant. It has been recom-

mended as a table plant, for which its light graceful style of growth eminently fits it, but at night, especially where exposed to changes of temperature, it goes to sleep, and its value for such a purpose is thus destroyed. Other species of *Phyllanthus* are very pretty and well worth growing, notably *P. nivosus*, whose leaves are arranged in the regular frond-like manner of the preceding. In this the foliage is green, mottled more or less freely with white, and a pretty loose-growing bush it makes; or, owing to the open style of growth, it may be used for furnishing a pillar or rather in the stove. *P. atro-purpureus* is a good deal in the same way, but with purple foliage. *P. Chantrieri*, more after the manner of the *Reidia*, is a larger-growing species. All of the above are of easy propagation and culture, but they need the temperature of a stove for their full development.—H. P.

#### NERIUMS.

THE better-known name, perhaps, under which this genus is cultivated is that of the Oleander. This is, however, only the specific and not the generic name. One does not meet with this at one time popular plant nearly so often as it deserves to be. Of its beauty there can be no question when well managed. Failures to

A double-flowered *Nerium*.

flower it successfully have no doubt caused it to be less grown than formerly. It is a plant that delights in an abundance of light; hence a sunny position should be given it. This not only tends to develop and solidify the current season's growth, but it also acts favourably in bringing the flowers to perfection. It is not difficult to induce a *Nerium Oleander* to show flower-spikes, but these often, from want of sunshine and warmth, do not open, rarely getting beyond the partially developed bud stage. Want of water during growth will tend to the same end. This may even take place without the plant actually suffering, but a sickly hue will pervade the foliage in this case; whereas if grown in a shady house the foliage may be of a dark green tint, yet no flowers will be produced. In this respect it is somewhat analogous to *Adiantum cuneatum*, which, if grown in heat, moisture and shade, produces fine healthy-looking fronds, which will not stand the test when cut. The *Nerium* if grown in a light house will develop foliage of smaller size, paler green in colour, but perfectly healthy, the wood being short-jointed. Such wood as this will the following season be almost sure to result in plenty of flowers before the young growth becomes too sappy to deprive the flower trusses of their share of

sustenance. The spikes are terminal, three woody shoots usually issuing from their base. If these are seen to be pushing away too freely it is better to stop them and rely upon back breaks. During growth an abundance of water should be given, with an occasional stimulant to pot-bound plants. Peat and loam make about the best compost, solid potting being practised; too rich a soil will tend to a woody rather than a free flowering growth. Cuttings may be easily struck in a little warmth by placing the shoots in bottles of water in a shady and moist place. Scale is oftentimes troublesome, but the usual remedies for it suffice. Towards the autumn a warm position outside will aid in ripening the wood for another season.

Some few years back I remember to have seen several distinct forms (of Continental origin, I think) at the Royal Horticultural Society's Gardens, Chiswick. These at the time struck me as being a useful type of plant for conservatories, being particularly dwarf and profuse in flowering. It is not, perhaps, generally known that there are two white varieties, one single (*Sœur Agnes*), another double (*album plenum*). Other good forms are *cupreatum*, the copper-coloured variety; *Felix Bourguet*, very free, saffron and rose; *Madonna grandiflorum*, creamy white, double, extra fine; *Professor Duchartre*, rosy purple, double; and *Double Rose*. GROWER.

**New Fuchsias.**—On p. 330 "H. P." complains that the new Fuchsias "sent out within the last few years have been principally remarkable for the size of their flowers. In common with many other subjects, the production of huge blooms seems to be the one object aimed at by the raisers." This is a somewhat sweeping assertion, and "H. P." being a careful writer has, no doubt, grounds for what he states. But I think he can scarcely be acquainted with the varieties raised during the last ten years by that well-known grower, Mr. James Lye, Clyffe Hall, Market Lavington, Wilts. The distinguishing features of Mr. Lye's new varieties are their free, yet compact growth, forming naturally symmetrical bushes and their marvellous freedom of blooming, the blossoms generally medium-sized. Their profusion of bloom is their leading characteristic, and I can say as a frequent judge that I find Lye's Charming, which I take as representative of his own raising, almost invariably forming one of six, four, or two plants, and it is often shown as a single specimen. I write this much in justice to a painstaking and successful raiser and cultivator who has done so much for the improvement of the Fuchsia.—R. D.

**Lilium longiflorum variegatum.**—When *Lilium longiflorum* and its several varieties are grown together the difference in their foliage, which is most marked when they are from 6 inches to 1 foot high, is very noticeable, some running up comparatively spare of leaves, while in others they are numerous, much longer than those of the taller forms, and reflexed in such a manner as to form a very graceful and symmetrical-shaped specimen. Among the bulbs imported from Japan a variety in which the leaves are edged with yellow occasionally crops up, but its ornamental features are not of a very high order. The reverse, however, holds good with regard to the variety *album marginatum*, whose leaves, which are somewhat more glaucous than those of the common kind, have a regular and clearly defined margin of white. I was recently very much struck with a few beautiful examples of this which

had been brought on in a greenhouse, and were about 1 foot high and much the same in diameter. They were perfect little specimens which would be sure to attract attention. These particular bulbs crapped up in a box of the ordinary *L. longiflorum* as imported from Japan.—H. P.

## ROSE GARDEN.

### AMONG THE ROSES IN MAY.

BAD as was the outlook among Roses after the frost broke, they are certainly looking much better now than many of us expected. Serious blanks are evident in almost all gardens, and young plants seem to stand better than those with old bark and which one might almost expect to be proof against frost. Caterpillars and grubs are appearing in great numbers upon my plants, and I have therefore had several turns at hand-picking. Nothing destroys these pests so well as careful and periodical hand-picking for a short time. A few days ago I noted that the Gooseberries were attacked with those small caterpillars so prevalent upon this fruit in some seasons. I syringed them with a fairly strong dose of insecticide and found it very deadly. Having a little of the solution left over, it was used upon a wall of Roses where the Rose grub was thicker than usual, and here also it answered its purpose admirably. As a rule, it is somewhat wasteful to syringe for this pest in the open. Roses that escaped the frost are not breaking with anything like their usual vigour, and this applies more particularly to the Hybrid Perpetuals. The Tea-scented and Noisette sections certainly possess greater powers of recuperation after serious checks or injury, and are now presenting a far more promising appearance than the Hybrid Perpetuals. The hardiest climbers of this section have proved to be *L'Idéal*, W. Allen Richardson and Kaiserin Friedrich. Mrs. Paul has stood well, but it is not breaking so strongly as I expected. A peculiar feature I have noted is the success with hedge Briers planted previous to the frost and the loss sustained among those budded. One might reasonably have expected that the rooted and longer-exposed stocks would have withstood the trial best, but it does not prove to be the case. The new forms of *R. rugosa* from France stood it well. I had them just before the severe weather set in, and planted them at once. They had a severe test, and turn out equally hardy with the well-known older forms. I note that several people have complained of Crimson Rambler being less hardy than was anticipated, but my plants have certainly come through quite as well as the majority and seem almost uninjured. When the weather looked so bad for our Roses, and in anticipation of many losses, I grafted an extra lot of the more tender varieties both from the Teas and Hybrid Perpetuals. These are now turned out of their 2½-inch pots into a prepared bed, and have a very promising appearance. I fully expect them to make nice stuff by the autumn, and shall follow up this plan in future. It is the bottom eyes of our dwarfs that we are most dependent upon, and never more so than this season. In grafted plants we usually have a dormant eye; if not, one soon pushes from around the first growth, and it is this that I am depending upon in this case. No Roses look so well as the dwarfs, and in no other form can we be so sure of permanent success. Dwarf Roses, unless the variety be very tender, will always produce shoots from the base and make a show, whereas too often our standards and half-standards are killed outright. Even when

crippled, the last-named seldom come round in so satisfactory a manner as the bulk of dwarfs.

The maidens are now demanding a large share of attention, and have certainly come on better than was expected a few weeks back. Staking, tying, and a little moulding up of earth around the base, so as to cover the junction of the stock and Rose, are very necessary. It does not need much wind to break off the tender young Rose growth, especially if accompanied by a shower, when the foliage becomes heavy. The majority of our permanent beds have now been filled in with surplus pot plants, and it is an excellent plan to keep a few of these under slight cover for such a purpose. Standards in pots have been in great demand, owing to the extra loss among these, and I would strongly recommend any growers who must grow standards to have a few in pots ready for late spring planting. Where the precaution of giving a slight shade has been attended to, Roses under glass are looking well. None of the plants will be stood in the open air for a short time yet; it is so much better to be more sure of warm weather, and so avoid the risk as would follow from an exceptionally early autumn frost upon our free-growing Teas when in the open borders.

R.

**Rose Duke of York.**—This, one of the novelties of last year, bids fair to be of an exceptionally useful character. At its home at Messrs. Wm. Paul and Son's it is practically an all-the-year-round Rose. It was shown late last autumn in pots most profusely flowered at one of the Drill Hall meetings. This spring again it made its appearance in advance of everything else, and in the best possible condition. These same plants are now (May 7) flowering and in advanced bud for the second time. This variety is, therefore, to all intents and purposes a perpetual bloomer in the true sense of the word. The growth is moderate, even for a China Rose, yet very free and vigorous, *i.e.*, without any undue excess of stout sappy shoots. I have it both in pots and planted out, believing it to be a most serviceable variety. When first it was shown, the year previously, the flowers bore some resemblance to those of *Homère*, which in some measure they still do in form, but they are several shades deeper. Duke of York is, however, a better plant for pots. When it is more plentiful, this addition to the China Roses should prove to be an excellent bedding variety.—GROWER.

**Climbing Roses.**—In the majority of cases the crop of bloom from these has now been secured, and therefore we must give some attention to the production of the most suitable growth for next season. Too often these Roses are left pretty much to chance after their beauty is over. No after care will make up for neglect now, as unless we get good wood during this period of their growth we cannot possibly have bloom of the desired kind next spring. No period is more critical than that immediately following upon the great exhaustion of heavy blooming. To check the first sucker-like shoots from the lower part of our plants is to court failure, or at the least a late and immature growth. It is very necessary to help them with liquid manure, and not to forget how necessary sufficient moisture is at this season. Let the manure water be given liberally, but not too strong. I know of nothing more annoying in Rose culture than to discover that a healthy and vigorous plant is gradually declining solely because one has been too generous with what was intended to further improve and support the growth. Cleanliness, secured by frequent syringing with soft water, is also a great aid.—R.

**Pot Roses at Messrs. Wm. Paul and Son's Waltham Cross Nurseries.**—Although this old-established firm has long ceased to enter the competitive lists, it must not for one moment be inferred that Roses in pots are not grown. The

huge specimens of former years have given place to others of more useful size, and instead of the one-sided style of training which by most exhibitors is still adhered to, we have shapely all-round bush plants of various sizes, the smaller with from ten to a dozen fine buds and blooms, and the larger with as many as five and six dozen, which promise to be of the best possible quality. It is pleasing to note this all-round style of pot Roses, with no stiff, cramped or formal mode of training. The plants are chiefly grown in two large span-roofed houses, which upon one of the warmest days of this spring struck one as being delightfully cool and comfortable compared with the outside temperature. The plants are elevated on pots at a considerable distance from the glass, but through the houses being very light and the ventilation judiciously controlled, there is no semblance of elongated growths.—GROWER.

### SLUGS.

LIKE Mr. J. Whitworth Shaw (page 334) I have an abundance of slugs, although the winter was so abnormally severe and prolonged. Fortunately, the spell of hot sunshine now experienced gives tender plant growth a chance of making some headway, otherwise the outlook in the vegetable garden would have been serious. Young Cabbage, Lettuce and Cauliflower plants, put out from sowings made under glass, disappeared as if by magic, soot and lime being absolutely useless while the rain continued daily. Some mid-season sowings of Peas shared a similar fate. Out of half a dozen long rows there is not sufficient for making two, and this in spite of daily hand-picking, which seemed the only practical remedy. Nor were slugs the only enemy I had to deal with, for I do not remember before witnessing such a number as there was, in the evening following a showery day, of large earth-worms. Mr. Shaw remarked that to all appearance it had rained slugs. I think he would say equally that there must have been a rather heavy shower of large worms, so numerous were they spread over the surface. Fresh-planted seedlings had no chance whatever against these, for there were large numbers of them to be found in the early morning, roots instead of heads uppermost, and drawn into the large worm-holes. There is no doubt that the large worm-holes were convenient hiding-places for the slugs during the day. The evils of Box edging have been only too apparent this spring, thousands of seedling plants being devoured from beds adjoining paths furnished with this as an edging. Much the best remedy I found for dealing with slugs was nitrate of soda, after the stormy weather abated. Some of this was purchased for stimulating a quick growth in the Cabbage and Asparagus crops, both being late, the former also being very patchy. The first to receive a dressing was a young plantation that had been repeatedly filled up through losses by slugs, and the utmost satisfaction was felt when in the morning large numbers were found on the surface soil quite dead. Possibly salt might have had a similar effect, but I do not think it would have been equal to the nitrate. An investment in either would have been justifiable if the destruction of such a troublesome plague could have been assured. On the score of economy and safety I found it necessary to pass the soda through a rather small-meshed sieve, so that the lumps, of which there is always such a quantity, could be pounded with a mallet. Put on in the state in which it usually comes to hand, there is a danger in small seedling plants being killed outright where the larger lumps dissolve immediately on their roots. After the experience of the past winter, there will be no future hope of slugs being destroyed by frost, no matter how severe or protracted it might be, because in my case there was but little snow to cover the ground as a protection to them, nor were they out of the reach of frost unless they penetrated to quite 2 feet or more into the soil. That they remained alive and healthy with only very slight shelter, I had unfortunately conclu-

sive evidence; boards and planks for wheeling on if upturned disclosed only too plainly that they need not burrow deeply to get beyond its influence. There is generally an idea that a severe winter destroys numbers of slugs in the garden, but such a hope must not be entertained again, for it is doubtful if ever there will be a winter affording such convincing proof as that we have had.

Ground occupied with Brussels Sprouts, winter greens and Celery trenches seems to be the favourite feeding quarters of slugs during the season. On ground just cleared of the two first named crops much the larger number of slugs has been found, and the least is on that freshly-dug, which points rather to the fact of their extermination by deep digging. Last year Parsnip and main-crop Carrot seeds were first sown on firm undug ground, but until this was dug I could get no "plant," slugs eating them off as soon or even before they had sprung up; the second sowing did very well on the same border when dug. Probably had I sown a dressing of salt or nitrate of soda with the seed in the first instance, I should have been spared the necessity of digging.

W. STRUGNELL.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

TEMPLE SHOW, MAY 21, 22, AND 23.

#### Orchid Committee.

First class certificates were awarded to—

*CYPRIPEDIUM STONEI PLATYSENIUM*, of which great rarity a very finely grown plant was exhibited with two spikes of its handsome and most singular flowers, each spike bearing two magnificent blooms. The dorsal sepal is creamy white with bronzy purple lines, the lower sepal being almost equal to it in size and marking; the petals, which are one of its chief characteristics, are very broad and of great length, being very similar in colouring to the sepals, the purple shading being of the two darker; the lip is long, as in the type, white, with deep rosy tints. From Sir Trevor Lawrence's collection.

*ODONTOGLOSSUM (MILTONIA) BLEUANUM VIRGINALE*.—A most lovely form of *O. Bleuanum*, more beautiful in its extremely soft tints, whilst the flowers are nearly 5 inches in width, the colour of which is pure white with a light rosy tint at the base of the petals, and slight veins of a darker shade upon the base of the lip. This was also a finely cultivated example, having also travelled well. From Mons. Jules Hye-Leyen, Ghent.

*CATLEYA MENDELI BELLENSIS*.—A most charming and distinct form of this beautiful species, amongst which it must be classed as one of the very finest; the labellum is of great breadth and well expanded, having a heavy blotch of deep rich purple and deeply fringed; the throat has the distinctive feature of Mendeli intensified in deeper shades of orange and yellow; the sepals and petals are rosy lilac, the latter being of great width. From Baron Schröder.

Awards of merit were adjudged to—

*CATLEYA MENDELI GRANDIS*, a notable form, with flowers of unusual size, the petals being of great breadth, these and the sepals being of a soft, rosy blush shade. The lip is specially fine, with deep colouring, its breadth adding to its beauty here. The rich purple is very fine, the golden markings in the throat being also very distinct. From Messrs. H. Low and Co.

*CATLEYA MOSSIE LADY F. WIGAN*.—An extremely beautiful form, with very soft tints of colouring; the sepals and petals are pure white as in *C. Mossie-Reineckiana*, but the colouring of the lip is much lighter, the rich purple blotch giving place to veins of the same shade. The fringe, so noticeable in *C. Mossie*, is pure white; the rich yellow of the throat is most conspicuous. From Sir F. Wigan.

*CATLEYA LAWRENCEANA ATRO-RUBENS*, of which a small plant only was shown, but this was quite sufficient to stamp it as one of the finest forms of this richly-coloured species yet seen. The colour of the lip, as usually noted, has been imparted to the petals, whilst the sepals are a shade lighter. The lip itself, on the other hand, is several shades deeper, the rich, deep rose-purple being singularly unique and fine. From Mons. Jules Hye-Leyen.

*LÆLIA PURPURATA BELLA*, which in a measure takes after *L. p. Russelliana*, the lip only having a shading and slight veins of purple, the latter of a darker shade. The sepals and petals, also the ground colour of the lip, are of the purest white, being also fully up to the usual size of the species. From Messrs. W. L. Lewis and Co., Southgate.

*ODONTOGLOSSUM PISCATOREI LA PERFECTIO*, which is quite a gem amongst *Odontogloss*, with the usual, but larger spots and blotches of this species of a rich shade of rosy purple, the colouring of the labellum at the same time being darker still. It is a very finely-marked form, with the flowers also of extra size. From M. Vuylsteke, Belgium.

*ODONTOGLOSSUM WILCKEANUM VAR. LOWI*.—A very light-coloured form of this species, the sepals and petals being of a pale primrose shade, the sepals spotted with dark oak-coloured spots and barred also with the same shade; the spike was a fine one, although the plant was not itself large. From Messrs. H. Low and Co.

*MASDEVALLIA HARRYANA MINIATA*.—A singularly fine form of this beautiful species, its large flowers being very conspicuous in their rich shades of colour, which is an intensely deep scarlet, with a suspicion even of vermilion. This form stood out as a most distinct variety amongst the number of other *Masdevallias* shown by Sir Trevor Lawrence.

*MASDEVALLIA SHUTTRYANA (M. Shuttleworthi × M. Harryana)*.—A most pleasing hybrid of comparatively dwarf growth; the colour is a rich orange-red, with a suffusion of golden yellow, the tail-like appendages indicative of *M. caudata*, of which *M. Shuttleworthi* is a form, being bright yellow. Also from Sir Trevor Lawrence.

Botanical certificates were awarded to—

*VANDA CONCOLOR*, a rather dull-coloured species having cinnamon-coloured sepals and petals; this appears to be a form of the old *V. Roxburghi*; and *Brassia Keeleana tristis*, with singular-looking flowers, the sepals and petals being of a shade between green and brown and the lip white. Both from Messrs. B. S. Williams and Son.

#### Floral Committee.

First-class certificates were awarded to the following:—

*DRAECENA GODSEFFIANA*.—A distinct species of tall growth, with cane-like shoots and oval leaves of a dark green colour, blotched and spotted with pale yellow. From Messrs. Sander and Co., St. Albans.

*INCARVILLEA DELAVAYI*.—A fine new hardy plant from China, with large bright rose-coloured flowers, in shape like those of a *Martynia*, and borne several in a cluster at the top of an erect stem 9 inches high. Shown by Sir Trevor Lawrence.

Awards of merit were granted to the following:—

*CALADIUM LORD DERBY*.—The leaves of this are of medium size, of a rosy red shade, the veins and edges conspicuously delineated in deep green. Shown by Messrs. J. Veitch and Sons.

*CALADIUM HENRY IRVING*.—A pretty variety, the centres of the leaves silver-grey, with broad green margin, the veins of a rosy shade. This also came from Messrs. J. Veitch and Sons.

*CALADIUM ROSE LAING*.—This is a tall-growing kind, with immense leaves of distinct colour, chiefly greenish white, but prettily suffused with pink about the centre. Shown by Messrs. J. Peed and Sons.

*PHYLLOCTYUS EXCELLENT*.—This charming kind has large, broad-petalled flowers of a brilliant

orange-scarlet colour, with crimson edging to the petals. From Messrs. J. Veitch and Sons.

*PÆONY LORD IVEAGH*.—A fine Tree *Pæony*, with large semi-double flowers of a rich cerise-red colour. Shown by Messrs. Kelway and Sons, Langport.

*GLOXINIA PRINCE OF WALES*.—A large flowered, brilliant self variety, with flowers of a deep crimson colour. From Messrs. H. Cannell and Sons, Swanley.

*CLEMATIS DUCHESS OF YORK*.—This is another of the *C. coccinea* hybrids, and a charming kind of a soft blush colour with a deeper band of pink down the centre of the petals, which vary in number from four to six in each flower. Shown by Messrs. G. Jackman and Sons, Woking.

*BEGONIA SAMUEL POPE*.—A double-flowered kind of a creamy hue, the petals edged with bright rose. Shown by Mr. T. S. Ware, Tottenham.

*BEGONIA WHITE CAMELLIA*.—A pure white double-flowered kind, aptly named after the flower it much resembles. This also came from Mr. Ware.

*BEGONIA REX, MASTERPIECE*.—A dwarf-growing kind with numerous small rounded leaves of a dull red shade, the stalks and leaf veins bright red, the edges of the leaves dark green spotted with red. Shown by Messrs. F. Sander and Co.

*BEGONIA LADY ANNESLEY*.—This has a beautiful leaf, with a bluish tinge about the centre and a broad zone of silver-grey, margined with light grey-green. From Messrs. F. Sander and Co.

*PELARGONIUM DUCHESS OF YORK*.—This is a pretty tricolor variety, the leaves grey-green in the centre, with a bright zone of soft clear red margined with yellow. Shown by Mr. J. Prewett, Hammersmith.

*SIETHORPIA AUREA VARIEGATA*.—A variety with leaves of a pale yellowish green colour in pretty contrast to the silver variegated form shown with it. From Messrs. J. Backhouse and Sons, York.

#### Fruit and Vegetables.

Messrs. Rivers and Son, Sawbridgeworth, had a group of twenty-five very fine pot Nectarines laden with fruit, each tree having from twenty to thirty fruits of splendid quality and grandly coloured. The varieties were the new Early Rivers and Cardinal. Early Rivers is noted for its earliness and good qualities, either forced or in the open. Cardinal is distinct, the fruit being more blotched; this is a fine variety for indoor culture. Some large baskets of Cardinal were also staged with a tree of Lord Napier to show the early fruiting qualities of the Cardinal. Messrs. Bunyard and Co., Maidstone, sent sixty-five dishes of Apples. The collection was nicely staged, being backed by pot trees of St. John's Fig laden with fruit and alternate plants of *Spiræa confusa*. Some of the larger Apples were remarkable for their colour and firm appearance. Calville Rouge, a bronzy red fruit; Wagener, a new kind; Belle Pontoise, Beauty of Kent, Alfriston, King of Tompkins Co., Reinette du Canada, Duke of York, High Canons, Winter Peach, Striped Beaufin, Tibbett's Pearmain, Landsberger Reinette (very fine), Newton Wonder, Allen's Everlasting and Brownlee's and Egremond Russets were the finest.

Mr. Wythes, Syon House, Brentford, staged a dozen dishes of fruit, including Amsden June Peach, a good seedling Melon, and four fruits of Beauty of Syon Melon. A new departure, which it is hoped will not be followed at future shows, was to cut the Melons, spoiling their appearance and rendering them valueless to the exhibitor. This was done by the judges. Surely it is unnecessary to cut Melons in a collection of fruit not for competition. Grapes in three varieties, Sir J. Paxton Strawberries, Brown Turkey, Negro Largo and Bourjassotte Grise Figs, and Lord Napier Nectarines completed a very good exhibit. Mr. McIndoe, Guisboro, Darlington, Yorks, sent some eight dishes of fruit, including a grand dish of Lord Napier Nectarine, Dryden and Early Rivers Nectarines, Bellegarde Peach, Best of All and Premier Melons, a dish of Lemons

and Tomatoes. Mr. J. Friend, Rooksnest, Godstone, staged six bunches of Black Hamburg and Foster's Seedling Grapes, the bunches good and berries well coloured. Mr. Osman, Ottershaw Park, Chertsey, also sent Black Hamburg Grapes, large and well coloured. Mr. Featherby, Gillingham, Kent, sent a very good collection of fruit and vegetables, having well-coloured Hamburg Grapes, Hale's Early Peach, Covent Garden Cucumber, and Ne Plus Ultra Bean. Mr. Messenger, The Gardens, Woolverstone Park, Ipswich, sent a nice collection of fruit, including good Melons, Brown Turkey Figs, and Hamburg Grapes. Mr. R. Johnson, Stand Hall, Manchester, staged six bunches of Grapes, but not quite ripe. Mr. Miller, Ruxley Lodge, Esber, sent a collection of seedling Melons of nice size, mostly green-fleshed, and of good quality. Mr. Gilman, Ingestre Gardens, Stafford, sent a white seedling Melon named Early May, but not at its best. Mr. Farr, Spring Grove Gardens, Isleworth, sent a green-fleshed Melon named Beauty of Patsbuhl.

The vegetables call for special notice, the Messrs. Sutton, Reading, staging a great quantity of Peas in pots and Tomatoes. Rarely have such grand examples of vegetables in pots been shown. The Peas were equal to those grown in the open, and the Tomatoes were laden with fruit down to the soil. This collection occupied much space, and consisted of mostly new varieties. Bountiful, a round blue seeded Pea, 3 feet, was laden with pods, some fine examples being staged. Another variety, a very dwarf marrow, one mass of pods, the latter quite full, and 5 inches to 6 inches long, was the new seedling Marrowfat. This will certainly be a valuable addition to our early varieties, and is of very fine quality. This is the result of a cross between Royal Jubilee and American Wonder. Another new Pea was Sutton's A 1, a wrinkled marrow with true marrow flavour, 3 feet in height, containing seven to nine peas in a pod. Favourite was also grandly staged, the plants laden with fully grown pods. It is a true marrow, only 18 inches high, fine for forcing and pot culture. May Queen was represented by a dozen plants in 12 inch pots. This is one of Mr. Culverwell's crosses, and a fine Pea, very early, with marrow flavour, and some 2½ feet high. It is a very heavy cropper. Empress of India Pea was also shown in quantity. In size of pod it resembles Telephone, and grows from 3 feet to 4 feet high. It is a splendid variety for early sowing on warm soils. Tomatoes were staged in great numbers and in the best possible condition. A 1 Tomato was fine, fruit of great depth and in large clusters, somewhat after Ham Green. Best of All, a new variety of a deep scarlet colour, quite smooth and not at all coarse, is said to be very early. This the committee wished to be sent to Chiswick. Perfection was also staged in quantity and of good quality. Sunbeam, a yellow, oval shaped, new variety, was specially good. Tender and True, a new cross from the Peach and Perfection, was very interesting, and is specially recommended for dessert. Abundance and Dessert, two very fine types, were well staged; the latter had racemes of fruit with from ten to fifteen medium sized fruits on each. Golden Nugget still holds its own for quality. The new climbing Bean Tender and True was shown in 6 inch pots, showing its free cropping habit.

Mr. Wythes, Syon House, staged eighteen varieties of vegetables, mostly spring grown, having very good Veitch's Ashleaf, Early May and Victor Potatoes, Veitch's Model and Nantes Carrots, Early Milan Turnips, Perfection and Prelude Tomatoes, good Veitch's Model Broccoli, Golden Queen and Perfect Gem Lettuce, Asparagus, Ellam's and Veitch's Earliest of All Cabbage, Syon House and Ne Plus Ultra Beans, Victoria Spinach (spring-sown), Cucumbers, and Turnip-rooted Beet. Mr. Empson, Amphill House, Bedford, staged vegetables in quantity, with some Apples and Strawberries nicely arranged. Mr. Ward, Longford Castle Gardens, Salisbury, had a quantity of Harbinger Lettuces and First Crop Peas, large plants of Cucumbers trained to

various shaped trellises, Mammoth Asparagus, with a nice collection of Radishes in variety. Mr. R. J. Steel, Brentford, staged Rhubarb, Cucumbers, Lettuce, Beetroot, Leeks, and other small salads. Mr. G. Mount, Canterbury, sent three very nice dishes of Conference and Perfection Tomatoes. Mr. Waite, Glenhurst, Esber, sent very fine Asparagus. Mr. Trollope, Coombe Court, Reading, also sent some Asparagus.

### Tulips.

Tulips were very much to the fore. There was not a collection of cut flowers scarcely but contained Tulips of some sort. In addition there was the second exhibition of the southern section of the National Tulip Society, though all the best flowers came from the north, and there did not appear to be any indication that the flower is being much grown in the south. Still, so long as opportunity is offered for the Tulip to be shown as an exhibition flower in the south, it does not matter if the finest blooms are drawn from the north. But, judging from the scanty attendance in front of the stands even when the tents were most crowded, how very few persons appeared to be interested in them, refined and beautiful though they are!

RECTIFIED OR BROKEN TULIPS.—There were three collections of twelve rectified Tulips, that is, flowers which have passed from the sculling breeder or self state into the broken form, which is their permanent character. The best stand came from Mr. J. W. Bentley, Stakehill, Manchester, who has succeeded to the fine collection formerly grown by his uncle, the late Mr. Samuel Barlow. Mr. Thomas Haynes, Warwick, an old milland grower, was second, and Mr. C. W. Needham, Manchester, a promising young northern grower, was third. The exquisite refinement seen in the majority of these flowers contrasted strongly with the blooms shown in collections where the colour flooded too much of the ground. There were four stands of six varieties, and Mr. C. W. Needham was placed first. Mr. T. Haynes was second, and Mr. J. W. Bentley third. With three feathered Tulips, one of each class, Mr. J. W. Bentley was first, having fine blooms of bizarre General Grant, byblomen Guido, rose Comte de Vergennes. Mr. T. Haynes was again second. With three flamed Tulips Mr. T. Haynes was first, staging very fine blooms of bizarre Sir J. Paxton, byblomen King of the Universe, and rose Mrs. Lomax. The Rev. F. D. Horner, Burton-in-Lonsdale, was second.

BREEDER TULIPS.—These are seedling self-coloured Tulips which have not yet broken into their permanent character, though they may do so at any time, or it may not be for years. One could well desire that some would never do so, so beautiful are they, and it very frequently happens that the most beautiful breeders break into flowers of poor character, while those least attractive may rectify into blooms of fine quality. There are no more beautiful border Tulips than the breeders with their pure bases and brilliant colouring; by the side of them a large number of the Darwin varieties look coarse and unwieldy. The best six, two of each class, came from the Rev. F. D. Horner. Mr. J. W. Bentley was placed second. The Samuel Barlow prizes for the best pair of rectified Tulips, one feathered and one flamed, brought several collections, Mr. C. W. Needham winning the silver-gilt Flora medal with feathered byblomen Elizabeth Pegg and flamed bizarre Masterpiece. The Rev. F. D. Horner was placed second with a feathered byblomen seedling and flamed rose Mabel. The premier feathered Tulip was byblomen King of the Universe, from Mr. C. W. Needham; the premier flamed Tulip, bizarre Sir J. Paxton, shown by Mr. T. Haynes.

COLLECTIONS OF TULIPS.—Of these there were several, and they consisted of bunches of blooms placed in bottles of water. The best came from Mr. J. T. Bennett-Poë, Cheshunt, who had all the types represented by very fine blooms. Mr. J. W. Bentley was second.

### NOTES OF THE WEEK.

**Magnolia Soulangeana.**—We have received from Mr. F. W. Meyer, Exeter, a photo of a very fine plant of this Magnolia, quite a small tree and covered with flowers, growing in the gardens of Mr. G. Radford, Sidmouth.

**Two hardy Cypripediums** now flowering in the rock garden bog at Kew are *C. macranthum*, which is very fine, the flowers of a rich self rosy purple shade, the pouch large and much inflated, and *C. occidentale*, with twisted sepals and petals of a greenish brown colour, the pouch of a clear rich yellow.

**Strawberry Sensation.**—I send a few fruits of Strawberry Sensation to show what a large fruit it is. It is the largest I have ever forced, some samples weighing 1½ ozs. It is a solid fruit with fairly good flavour. The plants outside look well.—ALEXANDER TRAIL, Fulshaw Hall, Wilmslow.

**Aster alpinus superbus.**—There can be no reasonable objection to the name as regards this variety of *A. alpinus* which is now flowering at Kew. It is truly a superb form with a deep blue flower nearly or quite as large as that of *Erigeron speciosus*, and borne on a strong stem 6 inches or more in height.

**Hemerocallis Dumortieri** is a handsome Day Lily now flowering, and would make a charming companion to the paler yellow Day Lily. Its flowers are of a deep orange-yellow shade, bright and most distinct, the blooms borne boldly on a thick, erect stem. A coloured plate of this variety was given in THE GARDEN of March 26, 1887.

**Rosa spinosissima var. altaica** is a charming wild Rose now flowering abundantly at Kew. It is a native of Siberia, and although allied to the Burnet Rose, resembling it in spiny growth and tiny leaves, is more erect in habit, with very fine flowers of a creamy white colour. It is also known as *R. grandiflora* and is a most welcome early and showy kind.

**The Amethyst Hyacinth** (*H. amethystinus*) is one of the choicest flowers of the present week, welcome for its lateness when most spring bulbs are going to rest, and quite unique in its delicate shade of porcelain blue. Such gems as this are worthy of attention, and it is little that they need if planted under suitable conditions where they will be free from needless disturbance.

**Scilla pratensis.**—A group of this late-flowering species in one of the borders at Kew is noteworthy. It has tall, feathery spikes of flowers, small individually, but effective because so numerous; whilst in colour they much resemble those of the Amethyst Hyacinth. It is a native of Dalmatia and as elegant as the feathered Hyacinth, without the monstrous appearance of that flower.

**Rosa sericea.**—This is a lovely single Rose little known in gardens, but, judging from a large bush at Kew now covered with flowers, its merits only need to be made known, and, in common with many other single Roses, it will be sought for and planted. The bush is quite 8 feet high, making a handsome specimen, the arching shoots perfect wreaths of charming blossoms. The flowers are distinctly cruciform in shape, as they have only four petals about 2 inches across and of a pale cream or straw colour, passing to white.

**Camassia esculenta.**—This lovely bulbous plant ought to be popular in gardens, as it succeeds admirably under a variety of conditions, and has a prolonged flowering season. In groups among choice shrubs and left undisturbed for several years it is very handsome, and the spikes are much finer from such established groups. In Grass, too, it is happy. We noticed it this week in the wild garden at Kew flowering freely, its long spikes higher than the tall Grass, the effect especially charming in one spot where it was associated with the Star of Bethlehem, perhaps more by accident than de-

sign, but suggestive of a lovely picture on a larger scale.

**New Tea and other Roses.**—We have the pleasure to send you a box of Rose blossoms by parcel post which we trust will be safely received. The hybrid *Rugosa Mungo Park* is a cross between *General Jacquemont* and *Rosa rugosa*, and I send flowers of the last named for comparison. The other kinds enclosed are *Sylph* (Tea) and *Medea* (Tea). We have a high opinion of both these.—W. PAUL & SON.

\* \* The two Tea Roses are very charming. The hybrid is also interesting, but there is a vast difference in form and colour between such hybrids and the Teas.—ED.

**Tulipa Bouton d'Or.**—I send you five blooms of *Tulipa Bouton d'Or*, it is so good and such an old favourite in good gardens. When I was a child I then knew it as *Buttercup*. What do you think of the *Allamanda*-like gold? Is it not a beauty? and, what is more, when planted in good rich sandy soil and left, remains a "come-to-stay" plant. *Tulipa Gesneriana ixioideis* sent you last week with the black base, &c., was known fifty years since as the yellow Peacock Tulip on account of the zone being so like in colour that on the extreme tips of a peacock's tail, very green and dark.—W. B. HARTLAND, *And-Cairn, Cork*.

\* \* A fine Tulip, admirably grown.—ED.

**Absence of flowers on Ranunculij.**—The non-flowering of *Ranunculi* and *Anemones* is, I think, the consequence of the abnormally cold and wet summer of last year, which, though promoting a vigorous leaf growth, was not warm enough to ripen off the bulbs properly. Not only the above bulbs, but a great many more have not flowered well this year. Parrot Tulips have also flowered very sparsely with me, whilst last year, the result of the hot and dry weather of the glorious summer of 1893, these Tulips bloomed most abundantly. Many Irises are also very bad, and some have even died out entirely. Fortunately, the prospects are now somewhat brighter, as on the whole we have had a very genial spring, neither too cold nor too wet, and no late frosts.—C. G. VAN TUBBERGEN, JUN.

**Genista pilosa.**—In common with most of the early-flowering *Genistas* and *Cytisuses*, this species is this year blooming with extreme freedom. It is one of the dwarfest of *Genistas*, being of dense prostrate habit, and it is on that account especially useful for the rock garden and for making an undergrowth to other taller shrubs. A bed of *Caraganas* in the Leguminosae collection at Kew carpeted with this plant in full flower is now very pretty. The leaves are small and lanceolate, having the under surface covered with a closely pressed silvery down. The flowers, of a bright golden yellow, are produced in the leaf-axils of last year's growths. The species is a native of Britain, but it is not particularly common, being confined to dry, elevated tracts in the southern counties. It is, however, widely spread over the mere southern parts of Europe. It may be propagated by cuttings taken in July and August, or by seeds, which ripen in abundance most seasons.

**Cytisus purpureus.**—Nearly all the *Cytisuses* and *Genistas* have flowers that are white or yellow, or of some shade intermediate between the two, but in this species we have a distinct and welcome break. It is a shrub of dwarf, semi-prostrate habit, and just now its slender, graceful shoots are loaded with bright pinkish purple flowers. There is a variety with almost pure white flowers, and there are also others of a more or less rosy colour. The plant may be used near the front of a border, or as a kind of undergrowth to shrubs that are erect growing and do not obstruct the light too much. It can be easily increased either by seeds or cuttings, and is sometimes grafted on stocks of *Laburnum* to form standards. It is believed that the curious *Cytisus Adami*, which bears both the flowers of this species and those of the common *Laburnum* simultaneously, was originally produced in this way—one

of the very rare instances of hybridisation by grafting. *C. purpureus* was introduced a little over 100 years ago.—B.

**Rhododendron Smirnowi.**—This is one of the most remarkably distinct *Rhododendrons* introduced to this country in recent years. It is a native of the Caucasian Mountains (the Asiatic side) and has been known to botanists for about a dozen years. Some plants have lately been flowering in the arboretum nursery at Kew, and although nine years old they are as yet only 1 foot high. This dwarf habit is not, as might be expected, associated with small leaves or small flowers, some of the former being 4 inches to 5 inches long and 1½ inches wide, whilst some of the blossoms measure 2 inches to 3 inches across. The leaves are dark green above, but on the under surface are coated with a dark brown wool. Although the species has no pretensions to rivalry with the fine garden varieties now so abundant, it has several good qualities which might be taken advantage of by the hybridiser. It is perfectly hardy, and it is probable that if it were crossed with some finely coloured variety, its dwarf habit might be in a great measure retained and at the same time an infusion of brighter colour into its flowers secured. The flowers are of a rosy purple, and although large enough are somewhat loose in the truss, which is also as large as is found on any of the true wild species of *Rhododendron*.

**Exochorda grandiflora.**—One of the most beautiful white-flowered shrubs with us this spring has been a bush, some 6 feet or 7 feet high, of *Exochorda grandiflora*. It is a native of North China, whence it was introduced by Fortune, who first saw it in flower there in March, 1845. In the structure of its flowers it scarcely differs from a *Spiraea*. It was figured in the *Botanical Magazine*, t. 4795, as *S. grandiflora*. When it first ripened fruit, however, it was seen to differ sufficiently to form another genus. A coloured plate of it was published under the correct name in THE GARDEN, February 13, 1877. Although it is frequently grown as a wall shrub there is no necessity for any protection. It is quite hardy, and, provided it is planted in good rich soil, it seldom fails to flower after having once attained sufficient age and strength. Its foliage is of a rather light shade of green, the leaves being thin and quite smooth, narrow, oblong and toothed towards the apex. The flowers, produced in erect racemes, are each about 6 inches long and pure white. A single branch will sometimes have several flowering shoots produced closely together, thus giving the effect of one large snow-white inflorescence. Each flower is 1 inch across the slightly overlapping petals, making it round and full in appearance.

**Notes from Chester.**—We send a box of blooms of *Lilacs* and *Azalea mollis*, the latter from seedlings, simply arranged in order as to colour groups, and, roughly speaking, divided into reds and yellows, but the subtle gradations of tint prove the poverty of such an incomplete distinction and division. The yellows, as you will see, run through all shades of buff and straw colour to lemon and warmer tones, the reds through salmon-pink to brick-red. All are beautiful, and massed together they give broad patches of brilliant colour which cannot be surpassed, and which cannot indeed be matched by any other group of outdoor hardy flowering shrubs at this season of the year. The *Lilacs* are this year superb. Many people are unaware of the great variety there is in *Lilacs*. Years ago persons thought the ordinary *Lilac* which bloomed by the garden door, as *Walt Whitman* places it in his tender poem on the death of Lincoln, was the only type extant. But the various kinds now to be found in most collections show a splendid range. Amongst those sent you to-day, note especially *Ambroise Verschaffelt* with its bushy head of rosy pink. Contrast with this the pale lilac flowers of *Le Gaulois* and the robust vigorous shoots of *President Grevy*. *Conseiller Heyder*, *Cerulea Superba*, and *Gloire de Moulins* are all grand. With these we send a flowering spray of a beautiful silvery foliaged bush, *Eurybia*

*Gunniana*, with its simple flowers arranged so delicately and beautifully upon its perfectly symmetrical branchlets.—DICKSONS, *Chester*.

## PUBLIC GARDENS.

**Open spaces.**—The trustees of the London Parochial Charities have subscribed out of their surplus income for the year 1895 £1000 to the funds of the Metropolitan Public Gardens Association for the purpose of promoting the purchase or laying out of minor open spaces.

**Brockwell Park.**—This charming pleasure ground, opened by Lord Rosebery three years ago, is still inaccessible on the Brixton side. The delay in constructing an entrance through the Arlingford Road occasions much disappointment in the district; and a numerously-signed petition has been sent to the County Council through Mr. W. Haydon, L.C.C., asking that the proposed gate may be opened immediately after the land has been purchased. As the park is now seen at its best, it has been suggested that while the new gate is in course of construction, the inhabitants of Brixton might have access to the park by a temporary footpath.

**Metropolitan Public Gardens Association.**—On Thursday afternoon, Mr. George Matthey, F.R.S., the Prime Warden of the Worshipful Company of Goldsmiths, opened the St. Peter's Churchyard, Walworth, S.E., as a public garden. The ground has been laid out by the Metropolitan Public Gardens Association, the cost of the work having been generously defrayed by the Goldsmiths' Company. The Prime Warden, upon his arrival, was received by the Earl of Meath (chairman), Lord Teynham, and Sir William Vincent, Bart. (vice-chairman), and other members and officials of the association, together with the rector and churchwardens of St. Peter's, the members of the Burial Board and the Vestry. The Earl of Meath warmly acknowledged the handsome gift of £650 from the Goldsmiths' Company, which had been devoted to the preparation of the ground and the erection of a granite drinking fountain. He pointed out that the association had now laid out over eighty grounds, amounting to about 110 acres in extent in various parts of the metropolis at a cost of nearly £40,000. In Walworth much more is required to be done, as there were only about six acres of public open space for 116,000 inhabitants, or nearly 20,000 people to one acre of public space. The association was further engaged in endeavouring to secure another recreation ground in East Street, Walworth. Lord Meath concluded by presenting the key to the chairman, and desiring him to open the grounds.

**The weather in West Herts.**—During the past week the days have been very warm, but the nights, as a rule, rather cold for the time of year. On each of the last eight days the highest temperature in shade has exceeded 65°, and on four days 70°. The warmest day of all was the 29th, when 77 was registered. The lowest reading indicated by the exposed thermometer was 34°. Since the 21st the temperature of the soil at 2 feet deep has risen 5°, and at 1 foot deep as much as 11°. During the last four weeks only half an inch of rain has fallen, and the ground is becoming very dry. For the last two days no water at all has been through the 2½ feet of soil in either percolation gauge. *Rosa hibernica* came first into blossom in my garden on the 24th inst., which is eight days earlier than its average date of first flowering in the previous nine years, and ten days earlier than last year.—E. M., *Berkhamsted*.

**Names of plants.**—*John Morris*.—1, *Cypripedium Chamberlainianum*; 2, *C. Haynaldianum*; 3, *C. Argus*, fine form; 4, *Cattleya Mossie*.—*M. Ricardo*.—1, *Tulipa Gesneriana*; 2, *Tulipa Billietiana*.—*E. Semper*.—Yes, probably forms of *Tulipa Gesneriana*.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHIDS.

## AERIDES FIELDINGI.

THE genus to which this plant belongs is sadly neglected by Orchid growers, but possibly it is the most popular species. This is not to be wondered at, for it is a truly noble Orchid, and when in good condition is worth growing for the sake of the foliage alone, to say nothing of the handsome spikes so freely produced when its wants are understood and properly catered for. Many of the distichous-leaved Orchids do not bloom so freely as small plants, but this cannot be urged against *A. Fieldingi*, as the plants if in good health commence flowering when only a few inches in height, and each successive year grow stronger and produce larger racemes. The old system of keeping these plants in a hot dry atmosphere, reducing them almost to a state of flaccidity by entirely withholding water in winter, has, happily, become obsolete, and we now see what the plants are really capable of. Plants less than 1 foot high often carry three or four racemes each from 2 feet to 30 inches in length, and if such were more frequently exhibited in the trade groups at our principal shows, it would probably be the means of extending the culture of this section, and have the effect of lowering the surplus stock which is to be seen at many nurseries where Orchids are made a speciality. The racemes of this species are densely furnished with flowers, and owing to the graceful curve at which they are carried the plant is popularly known as the Foxbrush *Aerides*.

The culture of this plant is of the easiest, provided enough heat and moisture are at command. It may be grown in pots or baskets, either suspended or on the stage, and if there is no Orchid house it will do very well in an ordinary plant stove. The roots are very large and fleshy and must have a light and well-aerated medium, consisting of large nodules of charcoal and living Sphagnum Moss. The best time to give new compost is as soon in spring as possible, provided a brisk temperature can afterwards be maintained, so that the plants are not checked, but grow away naturally, the roots taking at once to the compost. Like the majority of this section, the roots are active, considerably in advance of the growths, and from the time the points are seen by the green tips to be moving, the water supply must be ample, and the atmosphere also plentifully charged with moisture and, if possible, ammonia. This is accomplished by damping the houses with liquid manure, strewing soot and lime in small quantities about under the stages, or in some cases by placing a little sulphate of ammonia in the evaporating troughs. Growth under these conditions will be very rapid, and small plants soon make good specimens if kept potted on. Towards the end of summer a little more air and sunlight should be afforded the plants to consolidate the growth, but no attempt at ripening, as the term is usually understood, must be made, nor must the plants be dried at the roots. When the points of the latter show, by the white portion closing over, that the season's growth is done, then the water supply must be diminished gradually, only giving enough in the winter to keep the foliage in good condition.

When repotting, if the roots are in a thriving state they will be found to have taken a very firm hold of the insides of the pots, and no attempt must be made to remove them. The pots must be broken and the old compost and loose potsherds removed piecemeal, those with roots clinging to them being replaced in the new pots. As many as convenient of the aerial roots should also be covered with the Moss. When, on the other hand, the roots are in a bad state through closeness of the compost or insufficient drainage, all decayed parts should be cut away and the plants repotted in clean potsherds, with simply a superficial layer of Moss, or they may be laid out on a moist stage, as advised for newly-imported plants, and when seen to be starting freely, potted or basketed in the usual way.

The chief insect enemies are the small brown scale, which attacks the foliage, and aphides, which nearly always make their appearance at flowering time. These are not very troublesome if taken in hand before they get numerous, and are easily kept under by the usual means. *A. Fieldingi* is a native of the Old World, being found in India and China, and I have referred to its culture somewhat in detail, as it is similar to that required for all the larger-growing members of the genus. H. R.

***Lycaste aromatica*.**—It is surprising the amount of bloom small plants of this species produce, the bulbs and foliage being literally hidden. On a moderately strong bulb I counted fourteen flower-scapes. The flowers are produced singly on these, and, as the specific name implies, they have a strong aromatic odour. They are, moreover, very long-lasting, and the plants withstand the dry temperature of living rooms much better than some Orchids. *L. aromatica* was introduced from Mexico in 1828, and, in common with all in the genus, thrives well in the cool house.

***Vanda Denisoniana*.**—This is interesting as being the only pure white *Vanda* we have. Several fine specimens of this were exhibited recently at the Temple show, all nicely in bloom. It is found growing on the Arraean Mountains at about 2000 feet altitude, and was introduced upwards of thirty years ago. There is a beautiful and distinct variety of this fine old species which, however, is still rare. In this the sepals and petals are sulphur yellow with numerous spots, the lip of a deeper shade of the same colour. This remarkable variety appeared amongst an importation introduced by Messrs. B. S. Williams, of Holloway, about ten years ago, but I am not aware of its having been brought home since.—W. H. G.

***Cypripedium caudatum*.**—*Cypripedium caudatum* is now flowering in several establishments around London, its long ribbon-like petals always making it attractive. The petals are longer in this species than in any other kind, in some instances reaching over 3 ft. in length, although, as a rule, on small plants the usual length is from 20 inches to 24 inches. The whole flower is of a yellowish colour, veined with a crimson brownish shade, and in the variety roseum the lip is heavily shaded with rose. The somewhat scarce variety Wallisi I noted with Messrs. Low and Co., of Clapton. This is similar to the type, but has rather smaller blooms, which are of an ivory white with greenish veins. The typical form is a native of the Andes of Ecuador, and enjoys strong heat and plenty of moisture under cultivation.—W. H. G.

***Oncidium Lanceanum*.**—This, although a difficult plant to grow, is certainly very beautiful when seen in bloom, and I recently noticed a fine well-flowered specimen in the collection of Sir F. Wigan, of East Sheen. This species belongs to that section of *Oncidiums* which produces no pseudo-bulbs. The leaves proceed from a stout rhizome and measure from 1 foot to 18 inches in

length and about 4 inches broad. They grow erect and are of a dull deep green colour, more or less spotted with dull purple. The erect flower-spike is produced from the base of the last leaf, and reaches a couple of feet in length. The blooms are numerous, and individually measure about 2½ inches in diameter, usually of a greenish yellow ground colour and spotted with brown. The plant above referred to was a remarkably fine dark variety, the sepals and petals being of a pretty shade of brown and spotted with brownish purple, the fine lip being of a deep clear rose. This Orchid was introduced as far back as 1834 from Dutch Guiana by the gentleman whose name it bears, and since by other collectors in British Guiana, where it is said to always inhabit the hottest and dampest places. I have had it doing fairly well when potted in a moderately sized basket, with fibrous peat and Sphagnum Moss, with plenty of drainage and suspended close to the roof of the Cattleya house.—W. H. G.

***Cœlogyne pandurata*.**—I was interested to see Mr. Knight's note on *Cœlogyne pandurata* with thirteen flowers on a spike in THE GARDEN of May 11. I have four plants of *Cœlogyne pandurata*. The largest specimen has three flower-spikes: one spike has fourteen very large blooms. Of the two other flower-spikes not quite out, one has twelve and the other eleven flowers.—W. DRIVER, Longford, Minchinhampton.

## STANHOPEAS.

WERE the flowers of Stanhopeas not so fleeting they would undoubtedly soon become very popular plants, as they are easily grown and very free blooming. The singular and grotesque-looking flowers are, moreover, just the class to appeal to Orchid fanciers, and they are also deliciously scented. About twenty species are described, all good kinds and worth growing, but those mentioned below are the most distinct and generally grown. The flower-scapes being rather short and proceeding in a downward direction, rather shallow baskets should be used, and these made open at the bottom. Wire baskets are often used, but those made from teak rods are just as suitable—in fact I have found them do better in the latter. A suitable compost will consist of equal parts of peat and loam fibre, with a liberal admixture of small crocks and charcoal, clean Sphagnum Moss being used to line the baskets and for surfacing. Some large pieces of charcoal must first be laid in the bottoms of the baskets and fixed as far apart as possible, the layer of Moss being placed over this to prevent the peat from swilling downwards. Stanhopeas thrive well suspended from the roof in the East India house, and require an abundance of water at the roots while growing, and the syringe must be used daily over the foliage to keep red spider in check. Although liking a clear light, the foliage will be injured by very bright sunshine, so that it is necessary to shade somewhat heavily at midday. Very little water is needed in winter, the Sphagnum absorbing nearly sufficient from the atmosphere to keep the plants from shrivelling. When well established in the baskets Stanhopeas flower freely, and as soon as the blossoms open the plants must be taken to a cool house and kept quite dry, when they last nearly a week, but the plants often flower three or four times in one season.

***S. BUCERHALUS*** is a well-known and handsome species. The pseudo-bulbs are dark green and the leaves broad, nearly a foot in length. The flowers are 4 inches across, with broad sepals and narrow wavy petals, bright yellow with crimson blotches. The column is white, spotted with purple; the lip is yellow, and has a pair of curved horns. It is a native of Equatorial America, having been first found by Mr. Hart-

weg growing on trees in Pocha, near Guayaquil, in 1844.

*S. DEVONIENSIS* was named in honour of the late Duke of Devonshire, in whose collection it first flowered. It is a large-flowered kind, orange-yellow in ground colour, thickly spotted and blotched with brownish crimson. The column and lip are white, the latter with a deep purple stain. A native of Peru, whence it was introduced about 1835.

*S. GRANDIFLORA* is a chaste and lovely Orchid, fairly plentiful in collections and deservedly appreciated. The flowers, pure white, with the exception of a few minute spots of red about the lip, frequently each measure 6 inches across. This is synonymous with *S. eburnea*, and is a common plant in British Guiana and Venezuela.

*S. BUONNUTA*, as the specific name implies, is remarkable in having no horns on the lip, as in the other kinds. The flowers are creamy white on the sepals and petals, lip orange-yellow at the base, paler in front. It is not often seen in collections, and is a native of the east coast of America. Introduced about 1845.

*S. INSIGNIS* is the species upon which Sir W. Hooker founded the genus in compliment to Earl Stanhope. The flowers are each 5 inches across, pale yellow, sometimes nearly white, spotted with purple. It is a native of Brazil, and first flowered in this country as long ago as 1827.

*S. OCLATA* is a variable, but beautiful kind, the flowers of different shades of yellow, usually spotted with lilac-purple. This flowers in the autumn, and is a native of Central America. Introduced in 1840.

*S. PLATYCERAS* is a native of New Grenada, whence it was introduced by Messrs. Hugh Low and Co., and flowered by the late Mr. John Day, of Tottenham, in 1867. The flowers are very large, pale yellow, with rosy lilac spots on the sepals and petals; the lip and column greenish white, marked with purple.

*S. TIGRINA* is a well-known and strikingly handsome Orchid, which has been known to cultivation more than fifty years, having been introduced by Messrs. Low and Co. from Mexico before 1839, when it was figured in the *Botanical Register*. The flowers are most peculiar in shape and variable in colour. This is usually dull yellow, more or less thickly spotted with purple. Another beautiful and graceful kind is

*S. WARDI*, the flowers golden yellow, spotted with crimson; the lip has a dark velvety purple blotch at the base. It is a native of Guatemala. Introduced in 1836. H. R.

#### SHORT NOTES.—ORCHIDS.

*Brassavola glauca* thrives well under the same treatment as the Mexican *Laelias*. It usually produces its blooms during the months of February, March and April, and the flowers last a long time in perfection. The sepals and petals are pale olive-green and the lip white.—G.

*Dendrobium Dalhousianum*.—This is one of the most stately *Dendrobiums*, and a kind that always attracts attention whenever seen in flower. The noeme carries five to nine large blooms, each upwards of 5 inches across; the flowers are nankeen-yellow, shaded and veined with rose, the concave lip having a large maroon blotch on each side near the base, fringed at the margin and somewhat hairy.

*Cattleya Skinneri alba*.—This is a charming companion to the typical form with its rosy purple flowers. A fine specimen with numerous spikes of bloom was shown by Baron Schroeder at the Temple. The flowers are quite as large as those of the type, pure white, with the exception of a small blotch of purple at the extreme base of the lip, which, however, is not noticeable as the blooms stand on the plant.—W. H. G.

*Lælio-Cattleya Hippolyte*.—This hybrid was shown lately at the Temple by several exhibitors, and under two names, some naming it as above, and others *Lælio-Cattleya Phœbe*. It appears to be a cross

between *Lælia cinnabarina* and *Cattleya Mossiæ*; the sepals and petals of a clear orange-yellow; the side lobes of the same colour, veined with carmine, whilst the front lobe is heavily blotched with velvety crimson.—W. H. G.

*Trichopilia crispa marginata*.—One of the handsomest kinds in this useful genus is the one here mentioned, and which is flowering profusely with Mr. J. Cypher, of Cheltenham. The flowers are large, the sepals and petals more or less twisted, of a deep rosy carmine colour, distinctly margined with a broad band of white. It requires a rather warmer temperature than the better-known *T. suavis*. It is known in many gardens as *T. gloxiniaeflora*.—W. H. G.

*Cypripedium Rothschildianum*.—Introduced in 1887 by Messrs. Sander and Co., of St. Albans, this remarkable and distinct *Cypripedium* has become quite a general favourite, and is now to be seen in nearly every collection. At the recent Temple show many fine pieces were staged, carrying several flowers of very bright and pleasing colours. A nice specimen with six blooms was particularly noticeable in the collection of Sir F. Wigan, of East Sheen.—W.

*Masdevallia Harryana luteo-oculata*.—This variety is very distinct, the flower being rich crimson-scarlet, with a striking large eye of bright yellow in the centre. This I recently noticed in the collection of Sir Trevor Lawrence, and also M. Harryana Mundyana, a remarkable variety with flowers of an intensely rich colour. *M. Harryana minima* is also one that stands out very conspicuously, on account of its rich vermilion shade and crimson veins.—W. G.

*Cypripedium calanthum*.—This beautiful hybrid was recently in flower in the collection of Sir Trevor Lawrence, Bart., the plant carrying nine fine blooms. It is a cross raised in Messrs. Veitch's nursery and flowered for the first time just fifteen years ago. The parents are *C. barbatum* Crossi and *C. Lowi*. It, however, has one serious disadvantage in that the leaves become spotted, these spots gradually but quickly increasing in size until the whole leaf is rotten and has to be cut away. In the specimen above referred to, however, the foliage was quite fresh and healthy.

## FLOWER GARDEN.

### PACKING BULBS.

A CORRESPONDENT from Wellington, some 400 miles to the north of this, writes to me to inquire about the proper treatment for *Narcissus cyclamineus* (1) in respect of transmission to the colony, and (2) as to the proper treatment on receiving it. He has imported bulbs from various firms and in every case has failed with them. Unfortunately, his experience so exactly coincides with my own, that I could offer no advice at first hand. I could only say that I have ordered bulbs this year from two different firms, and that with some of these, if they arrive safe, I intend to try a kind of half-bog treatment. As to the best means of transmitting bulbs like those of *cyclamineus*—which I suppose do not bear transmission so well as stronger varieties—my correspondent favours packing in cocoa-nut fibre. I daresay this would be a good medium for packing; the dry fibre would absorb any moisture thrown off in transit and so prevent decay. I have received such very critical things as *Hepaticas* in fibre, and though they arrived dust-dry and seemingly quite dead, many of them came round in time after lying dormant for eight months or so. I am bound to say, however, that a second consignment packed in a case with *Paeonies* and German *Irises*, where they must have had some moisture, came to hand in better condition and not a plant failed. My experience goes to prove that the best material for packing delicate bulbs is cotton wool. Mr. Ware packs small bulbs in this material and they arrive here in fine condition. Last year I received from Mr. Ware some score varieties of autumn *Crocus*, three bulbs of each. Each set of three was packed separately in a little paper bag in a nest of cotton wool. The

bulbs were small, like peas many of them, but with two exceptions they came out of their wrappings as firm, fresh and silky as when they went in. Varieties of *Snowdrop* in the same consignment did not fare so well; they were packed, if I remember, in hemp husks. At any rate they were carefully enough put up, but of six varieties only *plicatus* showed grass. Some were like dried fungus and went to powder in the hand. I may say that *Galanthus Elwesi* was not among the six varieties ordered. *Elwesi* and *plicatus* are the two *Snowdrops* that travel best and that thrive best in our climate. A useful lesson also in how not to pack was given in this consignment, and since I have mentioned the good points in Mr. Ware's system of packing, I may perhaps be allowed to point out where a mistake was made. Amongst other *Snowdrops* I ordered 100 of the common single and 100 of the double. Fine large bulbs of these were sent, but each 100 had been put without any packing material into a paper bag; the consequence was that one bulb infected the other because there was no absorbent of the moisture thrown off, so that when they reached me they were a mass of blue fungus with not a sound bulb amongst them. I suppose the reason for so packing the common *Snowdrops* in this way was that it would have taken up too much space to imbue them in a packing matrix of any kind, seeing that they had to be sent by post. Subsequently to this consignment I received another of *Daffodils*. Various *Corbularias* and such small varieties were again packed in cotton wool, each set in a little bag by themselves, and they all came in excellent condition. *Corbularia monophylla* had sprouted an inch or so in transit, the sprouts pushing their way through the wool, but they were not much the worse, for they have made healthy grass though they have not flowered. The other *Corbularias*, *conspicua* and *citrina*, flowered very well. Whilst dealing with this subject I might mention another instance of packing which struck me as worth noting. Some three or four years ago I received from Barr and Son some few species of *Anemone* which had been ordered on my part without any very certain hope of receiving such things in good condition. They were such varieties as *Pulsatilla*, *rivularis*, *blanda*, *apennina alba*, *memorosa* var. *Robinsoniana*, and *palmata*. Every one of these without exception reached me in a sound condition. Each species was separately done up in oiled silk (or some such air-tight material), so that there could have been no evaporation during transit. On being unwrapped from the covering the tubers, most of them a little sprouted, looked as fresh, plump, and moist as if they had been just dug out of their native wood or meadow. This, then, is apparently the way to send those stocky or tuberous roots which retain stored in them a large supply of nutritive matter, but which at the same time are impatient of being kept out of the moist ground. Now Messrs. Roozen and Son, of Haarlem, advise their colonial *clientele* (very properly and honestly, I think) of certain more or less choice things which it is difficult or impossible to send out to the Australasian colonies in good condition. The evidence of such a firm, with their enormous experience in packing for every quarter of the globe, ought to be incontrovertible and final. Yet facts are facts, and, backed by these, I venture to make my own comments on Messrs. Roozen's list, knowing that the firm will welcome all information bearing on their business. In the list of plants "giving nearly always a total loss on arrival," numbering in all eighty-four, occur such names as *Anemone memorosa* (all), *A. ranunculoides*, *Crocus*, *Galanthus*. I

have already mentioned my experience of various Anemones. As to what Messrs. Roozen say about Crocuses, I am surprised that such should be their experience; it is not mine. I should say that the cases in which consignments of Crocus go wrong are greatly the exception, and not the rule, that is, when the bulbs are well ripened, properly packed, and sent at the proper time. I once got a consignment of Crocuses myself from Messrs. Roozen. I cannot say I was very successful with them, but that was my fault, not the fault of the bulbs, which reached me in as sound a state as when they were lifted. If I had planted them at once in the open garden in somewhat light soil, I should probably not have lost a bulb, but acting on advice, I treated them otherwise, with some expense of trouble to myself, and lost them. Friends of mine who have had similar importations from this firm have saved every bulb. As regards autumn-flowering Crocus species, which I should suppose are more difficult subjects than the Dutch varieties, I have already mentioned my experience in importing them. As to Galanthus, I cannot say how such varieties as Fosteri, Parryi, Redoutei carry. I have received them only once, and though they were carefully packed, they were mere blue fungus when they reached me. But Galanthus plicatus, I should say, is a very transmittable bulb. So is Elwesi, and so are the ordinary single and double Snowdrops if they are carefully packed in some absorbent material like dry cocoa-nut fibre. Chinese Sacred Narcissus is one of the eighty-four "total loss" subjects. If the bulbs are obtained from China and then sent out here, it is quite likely that this bulb would fail. But they are plentiful enough here, imported direct from China and sold by Chinamen. No doubt alpine things like Saxifages and Gentians are not easily sent on so long a journey. I should think they could be sent out only in a Wardian case after having been thoroughly established in pots. On the other hand, such plants as the various aquatics, Calystegia, Dielytras, Ranunculus of various species, Trieyrtis, and others of the "almost total loss" list would probably travel very well if they were packed in oiled silk or some such material. Following this list of Messrs. Roozen's is another list of forty-nine species or genera of plants which "give more losses than the ordinary amount." On that list I have not much criticism to offer. Iris anglica is, I know, a very poor traveller. Lachenalias I should have expected to travel pretty well, but I have never imported them. I am a little surprised to know that Cyclamens give trouble. The only consignment I have had were of the hardy spring kinds, cum and its tribe (from Roozen), but these did very well, and this spring they have been pretty and attractive. The most interesting item to myself in Roozen's second list is "Fritillaria (various)." I should have expected the Fritillary to be in the list of "almost total loss." I do not know about the Crown Imperial section, but the various species carry very badly. F. Meleagris, the white and the chequered, and F. pyrenaica are fairly plentiful in my garden, but with the other species I have hitherto been unsuccessful. I should like to possess every Fritillary that grows, but I have come to the conclusion that these quaint flowers are not for us. All the same, I believe the bad success attending the importation of the Fritillaries is due to the "dry" system of packing. They are treated like Daffodil, Snowdrop, or Scilla bulbs, which may be completely dried off; whereas the Fritillary does not like being out of the ground even for a short period. Two or three months

of complete dryness so shrivels the tubers up as to destroy their vitality. If they were packed as Barr and Son pack the species of Anemone, in some material that would prevent too rapid evaporation, I believe Fritillaries would travel with perfect safety. It may be said that it would not pay a large and busy firm to vary its system of packing in this way to suit the requirements of various plants. But let bulb firms charge for any such extra packing. I am sure colonial buyers would be content to bear any reasonable charges of this kind. As it is, I calculate that the Fritillaries in my garden have cost me a thousand per cent. over catalogue prices.

Yet another experience in the importation of plants, this time of shrubby things. My belief is that most things of moderate size may be sent most cheaply, safely and expeditiously by parcels post. With the view of trying whether it would not be possible by this means to obtain the various species of Roses—our nurserymen can generally supply the sensation Hybrid Perpetuals, but for the most part ignore the species that have not been "improved"—I sent lately a small trial order to a home firm. The experiment was a signal failure, and for quite assignable reasons. First the grower would choose his own time of sending and not the time suggested by me. Home growers will persist in claiming to know the requirements of our season and climate better than we know them ourselves. If growers ever so far unbind themselves as to do what is requested, it is with a tone of protest, half of pity for our ignorance and half of irritation at being asked to do what they have not been accustomed to do. If they would only say, "No, thanks; your order is not good enough to make it worth our while, and you must go somewhere else," no one could have anything to object to. What they do in effect say is either "We will execute your order, but in our way, not yours," or "We will execute your order and according to your instructions, but permit us to insinuate, with as much courtesy as the delicate relations of seller and buyer permit, that you are a fool." To return to the order of Roses. As far as I remember I suggested that the proper time for packing the Roses and despatching them on their trans-equatorial trip would be the end of the English autumn or beginning of winter. It is true that growth might not have absolutely ceased by that time. There are some Roses in which growth never ceases, but most Roses have by the end of autumn laid in supplies and are ready for the winter sleep. If they are cut back sufficiently far for the requirements of the post and properly packed, they ought to do the six weeks' journey across the tropics without any fatal results. They would reach here about midsummer, and would start away growing at once without any further hesitation than a feeling of wonder that summer had come round so soon again. Despatched in November, they would reach here about Christmas or new year, a time when any stick of a Rose would grow right away and probably give an autumn bloom. Month passed after month, however, and I supposed the order had been forgotten. At length in March, when we are within measurable distance of winter, I got a letter and invoice dated February 7. The letter ran: "Here Roses go on growing and flowering until November, and some Chinas and others until Christmas; so it would never do to send them on so long a journey unripened. Now they are quite ripe and dormant, and it occurred to me that they would, sent now, reach you when your days are beginning to shorten." This is the kind of well-meant wisdom that is so exasperating to

those who order plants from home growers. As if we did not know what Roses did there in November and December! It is surely not the month of January that ripens wood in Ireland. Nor do we want to plant imported Roses when the "days are beginning to shorten and become cooler" ("beginning!" when we are within three months of the shortest day!). I only wish my Irish grower could have a little of the weather we sometimes have at midsummer, and he would find it cool enough for starting Roses. As for the invoice, it contained names to make the mouth water—Old Red Cabbage, pyrenaica, alba, and so on—the sorts of Roses one hopes to see again before one dies. When the box arrived some time after receipt of the invoice there was not a living Rose in the parcel. But though I blame the grower for not sending the Roses at the time I wished them sent, I do not blame him because the Roses were all dead on arrival. His packing was most careful, and the plants, as far as I could judge, had been good strong plants when they were put up. I have never received a consignment in which more care was shown. But for all that I believe the system of packing was a mistake. The Roses were put up on the "dry" system, firmly wrapped round with light soil and Moss and packed in a wooden box. There was too much room for evaporation. What happened was that the Roses had been baked on their journey as in a kiln, and so each plant was bone-dry. The system of packing would have been admirable for Cactuses, but some more moist way is necessary for woody things like Roses. If they had been packed moist they would probably have sprouted on the way, but they would not have been much the worse for that.

My Wellington correspondent also mentions incidentally another point about which growers on this side of the world have sometimes reason to complain. Instead of adhering to the terms of the order, certain things ordered are omitted and a double or treble quantity sent of something else. I cannot say that this has ever been my experience, but my correspondent mentions the name of a somewhat famous Daffodil grower (not English) who, in spite of remonstrance, repeated this style of treatment in a second order, and, to make matters worse, some of those sent were wrongly named. I suppose mistakes in naming are inevitable in the best regulated firms, but really such mistakes are sometimes surprising. For three years have I been nursing Narcissus tridynamus Duchess of Albany, and this year it promised a flower. Joy! expectation! daily watching of the bloom plumping. It is so large, so vigorous, really almost indelicately strong, corpulent—indeed, like a double. It bursts—it is a double! the common double yellow Telamonius plenus. I shall order Duchess of Albany again—perhaps, and in three years it may show flower—that is, seven years from the time of my first ordering the bulb.

Yesterday I received from Florida a small consignment of plants, which in its way serves to point a moral. With the exception of some half-dozen Orchids the plants were the easiest of all plants to transmit—Cactuses, namely. But really it was good to see how they came out of their swaddlings, each one as green, plump, and fresh as when it grew in Florida. Even the root fibres were white and fresh. Now, easy as Cactuses are to send, there is a wrong way of sending even these. Last year I also received a consignment from America (not from Florida), perhaps some two or three dozen varieties. They were packed in a case, and well packed, but sent first to London, thence to be shipped

hither. They must have been about three months on the way, and when they arrived the condition of some of them was shocking to see. What had been a fine plant of *Echinocactus Wislizeni* was a mass of decay, and others were just as bad. My mistake was in sending an order large enough to justify packing in a case, and I might give this "wrinkle" to those who send to the other side of the world for plants: "Let your orders be small." Yet if plant merchants would only execute orders as the Messrs. Reasoner Bros., of Florida, execute theirs, one might send an order of any size with the certainty of getting one's plants in the shortest possible time. They use somewhat long narrow boxes made of the thinnest possible wood, and therefore very light. Each box holds several plants and costs in postage 4 or 5 cents. I received five of these boxes, and the plants reached me in prime condition (probably within a month of their leaving the nursery) and exactly at the best time of the year, just as we are turning the spring equinox. The Orchids were almost as fresh as the Cactuses. Of course, this style of packing suits only such plants as are in some degree succulents.

FEBRUARY 12, 1895.—Since I wrote the above notes on various systems of packing bulbs for export I have received a letter from my Wellington friend, from which I venture to quote a passage:—

Since I wrote I have received *N. cyclamineus*—six bulbs. Four have grown, one of which has thrown up a flowering stem. They were packed in cocoa-nut fibre along with some varieties of *N. triandrus*, which had cardboard labels attached. The cardboard had become much mildewed and all near the labels were destroyed by the same thing. Fortunately, the bulbs of *N. cyclamineus* were far enough removed from the labels to escape. The labels should have been either wood or lead; the last is best. I have also had a package of herbaceous plants from M—— (principally varieties of *Lychnis*), who were instructed to pack in cocoa-nut fibre, not Sphagnum, but, like other English nurserymen, they think their own way better, and sent the plants packed in Sphagnum. The result has been almost total failure.

Yes, this is very exasperating. I think I almost prefer the treatment I receive from my own favourite London firm, to whom I sent an order for bulbs exactly eight months ago. Promptly by return of post I received an acknowledgment of my "esteemed remittance," with a civil type-written note intimating that I should hear from the firm by the next mail; and that is the last I have heard of my order. Still, I prefer that my bulb merchant should bank my "esteemed remittance" rather than send me stuff badly packed—*Lychnis* packed in Sphagnum, *per example*—or send me bulbs too late in the season. And thereby hangs a tale. On the same day, eight months ago, on which I sent the "esteemed remittance" for an order that has not yet been executed I sent another remittance for an order that has been executed, and well executed I am sure as regards the quality of the bulbs, though it came late beyond all my calculations, at a time indeed when I was some 2000 miles from home. Their interim treatment in white sand during my absence has, I am afraid, not been to their advantage. These were despatched from Ireland about November 1 (the invoice is dated October 24), and as the order was exclusively for Daffodils, it would, I think, be difficult to advance any intelligible reason why they had not been despatched a month or six weeks earlier. A. WILSON.

*Dundee, N.Z.*

**Hardy flowers.**—Judging by the number of inquiries made of the attendants at the hardy flower tables at the recent Temple show, it would seem as if the demand for various varieties was

still very great. So much the better; but whilst many have got almost everything, or at least know them pretty well, there are others who want hardy flowers for special purposes, such as for cutting to dress vases, &c., a purpose for which myriads of hardy flowers are specially fitted, but very many others are unfitted. A few selected from those in bloom in May shown at the Temple were as follows: *Thalictrum aquilegifolium*, in various shades of pale red or pink; flowers borne on tall stems and presenting roundish tufts of fine feathery petals, very light and pleasing. *Aster alpinus*, not more than 9 inches in height; flowers single, resembling those of a *Stenactis* in form and colour, a very charming thing. *Aquilegias* chiefly of the hybrid forms now so familiar, easily grown and very elegant. These seemed to attract great attention. *Achillea mongolica* has clusters of small single white flowers borne in great profusion to a height of some 2½ feet, a far prettier thing for cutting than is the double *A. ptarmica*. *Heuchera sanguinea*, now so well known, but hardly so perhaps is the beautiful deep rich red-flowered form known as *atro-sanguinea*, of which there were several fine bunches that were very effective. *Erigeron philadelphicus* has single flowers of a pretty rosy pink colour, and borne in clusters on stems 12 inches in height; these are very graceful and pleasing. The yellow-tinted *Euphorbia pilosa* gives very useful foliage for arranging with the flowers referred to. *Geum minimum* has single flowers of reddish orange, borne on stems 20 inches in height, and very pretty. The taller *Saxifrages*, such as *pyramidalis*, and even London Pride have elegant light flowers, whilst larger ones also very graceful are furnished by the perennial *Centaureas*, of which there are several colours.—A. D.

#### FLOWER GARDEN NOTES.

**COLOUR IN PLEASURE GROUNDS.**—In the notes on this subject in last week's GARDEN I omitted to mention that where large quarters of young seedling *Rhododendrons* exist, it is advisable to run through them once or twice while they are in flower to pick out any different shades of colour that are to be found. Sometimes even in very large brakes nothing fresh is obtainable, and then, again, one may go to another brake and find perhaps a dozen plants that differ considerably from the type, either much darker in colour, or almost approaching white. If some matting is taken, it can be fastened to any different shades that may be selected, and a variety in colour thereby secured either to form separate beds or for mixing with other things. Of course, the same end can be effected even more thoroughly by planting hybrids, but then the purchase of the latter where considerable quantities are required is a very expensive business. In the matter of *Azalea pontica* I should like to mention that a good stock of plants can be obtained by sowing seed in boxes or frames, and transferring to nursery beds so soon as the seedlings can be handled until the plants are sufficiently large to warrant putting them out in the open. It is rather late now for seed-sowing, but large bushes may be examined to see if any of the pods remain intact, and if this is so, a little seed may yet be sown, as young plants are always useful where there is the opportunity for planting flowering shrubs in quantity.

**MAY FLOWERS—PYRETHRUMS.**—The fine display of *Pyrethrums* at the Temple show recalls the time when the family was but scantily represented either as to quality or quantity, and now it is undoubtedly one of the best known May flowers. Although *Pyrethrums* will flower after a fashion on poor soil, they are not seen to advantage under such conditions, the foliage being weakly and the flowers of poor quality and scantily produced. Where the soil is naturally light and poor it is a good plan when planting to have a heap of partially decomposed cow manure at hand, incorporating this with the soil as the work progresses. It has a tendency to bind the soil a bit as well as to enrich it to give a little of the loamy consistency that is necessary to the successful

cultivation of this plant. A good surface mulching is also advisable at planting time, an operation, it may be added, that should always receive attention in the autumn, and not be left until the beginning of the year when growth is on the move. So soon as the first flowers are over the plants may be trimmed over a bit and receive if the weather is dry a good soaking of liquid manure; if showery, another mulching of farmyard manure will answer the purpose. This will encourage fresh growth and flowers, the latter in nothing like the profusion of spring, but yet sufficient to make the groups fairly gay. Any amount of varieties are now catalogued, but it is advisable to pick a few of the best in different shades of colour. *Aphrodite*, *Florentine*, *Leonard Kelway*, *Ormonde*, *Meton* and *Pericles* are a good half dozen.

**HEUCHERA SANGUINEA.**—The fact that this beautiful flower was also seen at the Temple show in quantity is a capital guarantee of its hardiness; it was later than usual this year, but flowered remarkably well. I have it on a very narrow border in small clumps associated with a special favourite (*Saxifraga umbrosa*) and the contrast between the spikes of the two flowers as they wave gently in the breeze is very pleasing.

**IRISES.**—The remarks made above as to the late flowering of the *Heuchera* are applicable to those Irises that commence to flower as a rule about the end of March. Instead of March flowering, however, few of them were out this year until the beginning of May, and are therefore, so far as 1895 is concerned, contemporary with the *germanica* section. All members of the *Iris* family are seen to the best advantage in a deep rather loamy soil, and once planted should not be disturbed. Given such a soil, they will last in capital condition for many years; indeed, individual clumps will go on increasing in size and in the quantity of flowers produced with each succeeding season. Like other plants of somewhat similar foliage and habit, as *Heimerocallis* and *Funkias*, they present a beautiful appearance when naturalised on grass, and in a cool, partially shaded spot very fine flowers and foliage are secured. It may be noted of this family that when using them for vase-work it is advisable if possible to put them up with their own foliage, a remark that also applies to *Paeonies*, another gorgeous May flower. Blooms of very large size, whether of peculiar shape, as the *Iris*, or globular, as the *Paeony*, look altogether out of character with tiny delicate foliage. Another point in connection with the best known families among herbaceous plants that is deservedly receiving increased attention is the advisability of planting each separate family together in considerable quantities. If large beds isolated on turf can be devoted to them, so much the better; if not, each should command at different points on the herbaceous borders sufficient space to show it off to the best advantage. A big gathering of *Pentstemons*, *Phloxes*, both early and late-flowering, and *Antirrhinums* well massed together in different varieties is immeasurably superior to a display of summer bedding plants.

**FLOWERS FOR WHITSUNTIDE.**—Since starting these notes there has been an application for flowers in great variety for church decoration for Whit Sunday, and nearly all the hardy things enumerated will come in very acceptable, white flowers being supplied—in addition to *Rhododendrons* of that shade—by *Deutzias*, *Guelder Roses* and the newer forms of *Weigelas*. The different shades of *Rhododendron ponticum* will help to furnish big masses of colour, large branches of the same being taken off to do duty as pot plants, and fine-foliage hardy and half-hardy supplied by *Bamboos*, *Cannas*, &c. As every gardener knows to his cost, greenhouse plants are practically crippled for the remainder of the season if employed in such work, and the utilisation of hardy stuff, where obtainable, is a great boon, besides producing for the brief period required an equally telling effect. The *Deutzias*, it may be noted, that are available are old forced plants that have been outside some two or three seasons, and are this year flowering very freely.

*Claremont.*

E. BURRELL.

**TUFTED PANSIES.**

THERE is a point in this appellation of these well-known hardy flowers that usually escapes notice, though often hardly criticised. It is the fact that the chief beauty of these plants lies in their tufted or clustered habits. Growers to display their varieties have taken to show flowers in spray fashion, and very pretty they look, but no method of showing them can less correctly convey what are the natural characteristics of these tufted Pansies. Even a bed full of small

beautiful all though the autumn. It is such masses as these which so fully justify the appellation now commonly given to one of the most charming of hardy flowering plants. Cuttings taken from the young shoots that break up so densely from old plants after being cut over in the summer and inserted thickly in sandy soil under a north wall or under handlights or in a frame, standing so all the winter and planted out as strong plants in May, will, if put out fairly close together, grow into very effective masses, although

*A hybrid Tobacco. Engraved for THE GARDEN from a photograph sent by Mr. L. Burbank, Santa Rosa, California.*

plants fails to show their value. Only when seen in large tufted clusters are the real charms of these flowers fully displayed. Those who want to see them at their best should plant early in the autumn and get the plants well rooted before the middle of winter. That is the way to have fine broad clumps blooming profusely in April, May and June, when usually *Violas* are seen at their best. If such clumps as these be cut over in July, have a liberal soaking of water and a top dressing of old pot soil given them, they soon get into flower again and are very

they do not show that same tufted quality that old plants exhibit. It is when grown in either of these ways that their value for ordinary border, bedding or rockwork planting is seen. Then, scores that are very pretty set up in sprays at shows are found to be of poor effect. If not of special value for such purposes, it is difficult to understand why so many of these tufted Pansies should be put into commerce. When the very best are secured, who wants the refuse even if in raisers' estimation ever so pretty? These plants have of late been receiving spe-

cial notice at Birmingham and from many diverse aspects. One thing merits especial attention. It is certain that, arising either from the introduction of more suitable varieties, or because our seasons are now less trying, tufted as well as ordinary bedding Pansies now seem to withstand southern summer weather better than formerly. I am referring to spring-planted plants, because there was a time in my experience several years since when these used to die off wholesale after hot weather set in. It was difficult to find the real cause, but one existed that baffled best efforts to find out. Soakings of water seemed at times to rather accelerate than check the evil. Whether due to a fungus or what cause could not be discovered. It was, however, an undoubted fact that the evil was rarely operative in the case of old plants or those put out in the autumn, and thus not only well established, but having several shoots or stems on them. Usually the disease, if it was such, was attributed to heat. If so, we ought to have seen these Pansies severely injured in 1893, but they did, having regard to the heat and the drought, pull through pretty well. I saw that year in Kent on an open, exposed site most beautiful masses of plants far excelling anything usually seen in gardens, and yet far removed from water. They were spring-planted, but chiefly of varieties introduced within the past six or seven years. It is, indeed, a great gain to be able to summer these tufted Pansies in this way in the usually too arid south. For such uses as are termed summer bedding, they now rank amongst the most persistent bloomers and the most beautiful. A few good sorts of distinctive colours suffice, and from these may be obtained effects of the most attractive description. A. D.

**A HYBRID TOBACCO.**

THE photograph of the very notable plant here figured Mr. Burbank sends us from his garden in California. He describes it as a hybrid between *Nicotiana glauca* and *N. glauca*, and much finer than either parent. Evidently the plant is worth inquiring about, judging from its growth in a climate like that of California.

**Losses in herbaceous plants.**—We have this spring to bemoan the loss of many valuable denizens of our herbaceous borders. *Romneya Coulteri*, which had made strong sappy growth at the end of the year, was cut to the ground, the mischief extending to the roots, most of which were rotten when the plant was lifted a short time since. Such roots as were sound were cut off and laid in damp cocoa-nut fibre at the shady end of the greenhouse, as recommended on page 101, vol. XXIX., of THE GARDEN. *Erigeron speciosus* (often known as *Stenactis speciosa*) and *E. mucronatus* (the Mexican Daisy), the latter an almost perpetual bloomer and quite a gem in its way, are dead, as are *Stokesia caryophylla*, *Scabiosa caucasica*, *Coreopsis grandiflora*, *Linum flavum*, and the Tree Lupin. These, with the many beautiful flowering shrubs that have been killed or badly injured by the severe winter, have made gaps in the borders, which it will be hard to adequately fill during the present year. Curiously enough, the slugs and snails, contrary to expectation, are more troublesome than has been the case for many years. While the arctic winter seems not to have affected them in the least, the ranks of their natural enemies, the birds, have been sadly thinned, which may in part account for the present visitation.—S. W. F., *Torquay*.

***Incarvillea Delavayi*.**—I note in your last issue of THE GARDEN that Sir T. Lawrence showed this plant in flower at the Temple show, and for which a first-class certificate was awarded by the Royal Horticultural Society. A very fine specimen of this rare Chinese plant was also exhi-

bited by Mr. Thos. Smith, of Newry, at the Lerne Bazaar, held in Dublin last week, where it was much admired on Mrs. F. Trouton's flower stall. The plant was growing in a pot and had been wintered in a cool house, but other specimens have passed through the late severe winter in the open air at Newry, and are now throwing up their leaves and flower-scapes. The flowering specimen referred to above had four or five very stout pinnate leaves 10 inches or 12 inches in length, of a deep green colour, and of leathery substance. The flower-stalk was 15 inches to 18 inches in height, and bore four to six very large rosy flowers not unlike those of *Bignonia grandiflora*. One curious point about the flower is the highly sensitive stigma, which is two-lipped, as in the genus *Mimulus*, and the expanded lips close quite suddenly on the stigma being artificially irritated. Although the plant is, under favourable outdoor conditions, perfectly hardy, the large tubular flowers do not appear likely to withstand high winds or heavy rains with impunity, and it may be wisest to treat the plant as half-hardy for the sake of seeing its showy flowers at their freshest and best. It is one of the most remarkable of new plants from China, and promises to become a valuable addition to greenhouse flowering plants.—F. W. B.

I have now in flower *Incarvillea Delavayi*. It is in the open border, where it has been a year or more, having stood the full brunt of a zero temperature. I have a smaller plant in a pot, but not so forward and not nearly so fine, a weaker specimen altogether. It has two stems, bearing a corymb (which will lengthen out into a raceme) of twelve or thirteen flowers, *Gloxinia* or *Bignonia*-shaped, tube  $2\frac{1}{2}$  inches long, limb  $2\frac{1}{2}$  inches across, delicate rose or rosy pink, throat yellow, streaked purple. I observe that Mr. Bain, Sir Trevor Lawrence's gardener, exhibited a plant at the Temple show raised from seed I supplied him with in 1893. He has sent me a flower which shows that my plant is the same, though raised from Charles Naudin's seed labelled *I. alpina*. No such name is known at Kew, and it is clear it is only a synonym.—Wm. THOMPSON, Ipswich.

#### PINKS.

THE cold weather and the accompanying dryness of soil and temperature are causing Pinks to spindle, that is, to throw up weakly flowering stems, whether it be the common garden varieties or the more refined laced Pinks. Unless warm rains and a higher temperature come soon, a fine head of bloom can scarcely be looked for. This is one reason why Pinks planted in the open in autumn do so much better than those planted in the spring, and especially is this true of the florists' laced varieties, and yet many persons do not think of ordering plants of Pinks from a nurseryman until April; and if they are supplied and planted thus late the flowers are rarely satisfactory. It used to be the custom with some trade growers of Pinks to winter some of their plants in 3-inch pots with which to supply orders in spring, and when these were carefully planted out and well looked after they produced good flowers, though they were never so reliable in the quality of finish as those planted out in autumn. It is sometimes said that the florists' laced Pinks are of no value for borders, but this is a great mistake, and made only by those who are imperfectly acquainted with their dense compact growth and freedom of bloom. Boiard, Empress of India, John Ball, Mrs. Thos. McCrorie, Modesty and Mrs. Waite are all capital border varieties. Other good border Pinks will be found in *Anne Boleyn*; *Ascot*, pink, with crimson centre; Mrs. Lakin, white, dwarf and free; *Alba magnifica* and *Snowflake*, two excellent white selfs, admirable for cutting (the three white Pinks just named do not split the calyx as do the common white and *Her Majesty*); *Souvenir de Sale*, deep, rosy pink; and of the small-flowered section, which are always so attractive at the Chiswick gardens—*Annie Bolton*, *Beauty*, *Charmer*, *Hetty Dean*, *Rosy Circle* and *Sir Hugo*. One of the incidents of the present

spring is the remarkable recuperative power shown by many of the garden Pinks. Where they were growing in somewhat low, heavy, moist land, plants suffered a good deal, but the hardy border varieties showed remarkable vitality, and plants which at one time appeared hopeless are covered with foliage and will bloom freely.

Then of the florists' laced varieties, a few of the very best will be found in *Clara*, laced with reddish purple, fine petal; *Rosy Morn*, rose lacing, large and full; *Harry Hooper*, rich dark lacing, a fine variety; *Boiard*, one of the very best laced varieties, very full, and a good grower; *Modesty*, pale rosy purple lacing, an early flowering and excellent exhibition Pink; *Empress of India*, rich dark lacing, a distinct and fine variety; *Duke of York*, a new midland-raised Pink, extra fine for exhibition, having a rich dark lacing; *The Rector*, heavily laced with bright reddish purple, extra fine; *Favourite*, heavily laced with reddish purple, extra fine; and *Princess Louise*, red laced, large and full.

Pinks do well in ordinary loam and road sand from a gravelled road and an abundance of well-decomposed manure. Old lime rubbish suits the Pink well, but as it is sometimes difficult to procure, road sand or gravel sand will do very well. Good Pinks always repay a mulching with manure in spring, and in addition to being a fertiliser, it keeps the soil about the roots cool and moist. The Pink being quickly susceptible to drought and injured by it, propagation is done at the end of June or early in July, pipings or cuttings being made of the young growths and rooted in sandy soil under a hand-glass or in a small close frame. Many growers layer their Pinks as they do their Carnations, and in this way they obtain strong, vigorous plants for planting out at the end of the summer to bloom in the May following. R. D.

### ORCHARD AND FRUIT GARDEN.

#### SELDOM-GROWN GRAPES.

OWING to the rage for large-bunched showy Grapes, many of the smaller-sized, though exquisitely-flavoured, varieties have gone out of cultivation, or are found only in isolated places. This is to be regretted, as in large establishments, at least where there is plenty of glass, a house might be devoted to their culture; and as some of them keep well when thoroughly ripened, a supply of these rich varieties might be had over a considerable time. Take the *Frontignans* for instance, both the *White* and *Grizzly* being of exquisite flavour and easily grown on a dry warm soil. The latter is not taking in appearance owing to its colour, but the berries are larger than those of the white variety, and it crops heavily. Both these Grapes are admirably adapted for pot culture. *Duchess of Buccleuch* is another free-growing and free-bearing Grape, possessing a flavour unsurpassed by any other, and producing long tapering bunches. The smallness of its berries is against it, and has no doubt prevented it from becoming popular. The *Duchess* is, however, well worth growing where room can be spared. Dr. Hogg—raised by the late Mr. Pearson, of Chilwell—is a deliciously-flavoured Grape, the bunch medium-sized, the berries rather small and round. This Grape also requires good cultivation and a warm dry soil, but this it will well repay. Mrs. Pearson and *Golden Queen* are also the result of the late Mr. Pearson's skill, both deserving to be more extensively grown than they are at present. Under good culture these will produce bunches and berries large enough for anything, and the liability of *Golden Queen* to become muddy when on the point of ripening may be overcome by giving the roots

a shallow, somewhat sandy rooting medium, and a light, airy house with plenty of heat. Mrs. Pearson has no such defect, and will, in my opinion, become ere long a leading white market Grape. Lastly, *Royal Vineyard* must be included in the list, as for flavour and keeping qualities it has no equal, *Muscat of Alexandria* not excepted. The wonder to me is that while some of the thick-skinned, indifferently-flavoured late Grapes are grown by almost everyone, *Royal Vineyard* should be so seldom met with.

All the foregoing are well adapted for pot culture or for growing in limited borders in small light houses where a certain amount of bottom heat could be turned on when the Vines were started. Canes sufficiently strong for fruiting can be grown in one season. Many think two seasons are necessary, but the fact is that in their anxiety to get extra strong rods, growers use far too large pots and give an unnaturally strong bottom heat. Such Vines lose many of their roots in winter, and although they may break strongly and look well while the stored-up sap lasts, they ultimately give way and produce inferior crops of Grapes. I have grown Vines in pots only 9 inches in diameter that have fruited well the following year. These had no actual bottom heat after receiving their second shift, and instead of being grown on in a stewing atmosphere, as is too frequently the case, they had plenty of air, and only an occasional syringing to keep them free from spider. In such sized pots the Vines can be fed without any fear of souring the soil, while the roots being numerous, hard and healthy, not only survive the winter, but are ready for action when started the following spring. If a light well-glazed lean-to house of medium size containing a bed furnished with hot-water pipes can be spared, so much the better, as the young Vines may then be planted out of 6-inch pots, grown on the first year and fruited the next. In such a structure their special wants can be attended to with comparative ease, and the comparatively small root run is conducive to a good set, high finish, and flavour. One amateur in the neighbourhood of London grows these *Frontignan* flavoured Grapes very successfully, and should others who have the convenience follow suit, they will find them to be not only highly interesting, but profitable. J. CRAWFORD.

**Apple Cox's Orange Pippin.**—The other day I was afforded an opportunity of inspecting the Apple plantations of Mr. Archibald Weir, near Ottery St. Mary, East Devon, and was much interested in what I saw. Mr. Weir's orchard lies at an elevation of 500 feet above sea level, and is on the side of a hill facing east. The soil, which has an average depth of 10 inches, and with which a large percentage of siliceous sand is incorporated, is light and porous and still contains a considerable quantity of water-worn pebbles, although many cartloads have been collected and removed. The staple may be tersely described as a sandy moorland soil. The subsoil consists of a ferruginous sand, into which the roots show no disposition to wander. At the first glance both site and soil appear eminently unsuited to the growth of Apple trees, but a survey of the 8 acres devoted to their culture, nine-tenths of which is occupied by Cox's Orange Pippin on the English Paradise stock, suffices to assure the doubter that the trees are happy. A plantation of seven-year-old trees has stems 6 inches in circumference, the lowest branches starting a foot from the ground-level and curving outwards and upwards to a height of 9 feet. The trees are open in the centre and have from seven to ten main branches, which are well ripened, short-jointed and carrying a good amount of blossom. These are the trees from which the splendid sample of fruit, averaging 9 oz. apiece,

which took first prize at the Exeter show in 1893, were produced, as well as many dozens that were sold to a West-end, London, fruiterer at 4s. per dozen, some of which fruits were subsequently re-tailed at 8d. apiece. There is no doubt but that Cox's Orange Pippin is thoroughly at home in Mr. Weir's grounds. Many other varieties have been planted experimentally, but none appear to flourish so satisfactorily, with, perhaps, the exception of five trees of Ribston Pippin, which were looking remarkably well at the time of my visit. The trees have had no manure, natural or chemical, either at the time of planting or since, nor have they ever been mulched, but poultry are allowed to run in the several plantations. No crops are grown between the trees, and, the ground being continually stirred, the surface is always kept loose. Mr. Weir admits the possibility of the trees not lasting, but as a contiguous orchard contains trees fully fifty years old, which are blossoming profusely and still look in the best of health, there seems no reason to fear a premature collapse. The plantations certainly do not suffer from lack of attention, but no amount of care will produce perfect trees and fruit of that prince of Apples, Cox's Orange Pippin, unless soil and situation are both to its liking.—S. W. F.

**Apple King of the Pippins.**—There cannot be any doubt as to the merits of Apple King of the Pippins, and which has been referred to both by "W. G. C." and Mr. Wythos. In this district it is largely grown for market, the farmers securing a good price for fine fruit. In fact, Prince's Pippin, the name under which this Apple is locally known, will always sell well. As to whether King of the Pippins and the true Prince's Pippin are synonymous, I now have doubts, although generally supposed to be. As evidence of this, at a show last autumn where I was one of the judges, in a class for six dishes of Apples distinct, King of the Pippins and Prince's Pippin were both staged, but although bearing a slight resemblance, they were both quite distinct. A local nurseryman also told me—and he showed me fruit to bear out his statement—that they were both distinct and that he could supply trees of both. So if a person applied to him for Prince's Pippin he would certainly not be supplied with King of the Pippins or Golden Winter Pearmain, although this might be the variety he required.—A. YOUNG.

**APPLE WELLINGTON, OR NORMANTON WONDER.**

AMONGST all the many excellent varieties of cooking Apples there is none that is in so much request by first-class cooks as the above variety for mince-meat, and, as a rule, gardeners are careful to retain it for that purpose. Again, as a market variety it is deservedly popular, as proved by the large demands by salesmen for it about Christmas and early in the new year. One salesman in the north of England informed me about two years ago that he should have no difficulty in disposing of 100 tons per week of Dumelow's Seedling—a name by which it is better known in that market than Wellington—in spite of all the foreign consignments, as even the most select Canadian or American varieties could not approach it for cooking and high quality. In face of these many good recommendations, it may be asked why it is not more grown to produce fruit in quantity for home consumption and market work. The reply to such a query is, that, unfortunately, the tree does not succeed in an altogether satisfactory manner on all soils. My experience of the variety is that it is the soil alone that is the cause of the trees not answering, as I have seen and had to deal with the variety in very exposed positions where few sorts of Apples would grow and bear, but Wellington rarely failed to be prolific annually, while on richer, deeper

soil, and apparently all in favour of the most successful results, the trees were very subject to canker, and made a weak, diseased growth. Provided a grower is certain that from actual experience Wellington will not canker and do well on his soil, I would strongly suggest planting it on a large scale, as few varieties will pay so well, having in addition to the advantages enumerated that of being saleable at any time from the end of September to the end of May, or even longer if stored in a good fruit room. At the latter season good and even samples will realise from 25s. to 30s. per cwt. through the hands of a salesman, probably more if consigned direct to a fruiterer doing a large business.

Returning to the soil and its effects on the trees, I believe that it points out to some element being deficient. It behoves the grower to try and discover what the lacking constituent may be, and then supply the same. On our light soil, bush trees exhibited great

Apple Wellington.

debility, and in spite of mulching with manure and adding fresh soil to induce a more healthy and vigorous growth, no improvement occurred until potash was applied. At first German salt or kaimit was employed at the rate of 4 cwt. or 5 cwt. per acre, but of late years I have used muriate of potash, as it contains a much greater proportion of the necessary element, railway carriage is less, and it is less labour to apply, as only about half the quantity is required per acre than with kaimit. Since applying potash a most marked improvement has taken place, growth being vigorous, the trees prolific, with fruit of high colour and handsome shape, as in the illustration. On heavy soil an application of iron in the form of basic slag might be tried with, I think, beneficial results. Some trees that I saw in Staffordshire had a dressing of 4 cwt. per acre, and the fruit produced the year after would have been highly creditable to the best district in the kingdom; in fact, I have not seen any better coloured Wellingtons than they were. However, only

careful experiments will prove what is the most suitable chemical manure to apply, as on some land none of the above might be of much service, and lime be the chief element absent. In such cases I would not apply ordinary lime, but give a dressing of bone-meal or superphosphate. By the above means, trees that are in an unsatisfactory condition may be greatly improved and so invigorated, that really good fruit of Wellington will in time become assured.

W. G. C.

**Strawberry Royal Sovereign.**—This new Strawberry is a great favourite with Mr. Salter, of Woodhatch Gardens, who now prefers it for early forcing to all others. The fruits come with him of great size, rich in colour, and of excellent flavour. He mentioned that but a few weeks back a local dealer expressed a desire to purchase for the sum of £5 the produce of twenty-five plants, picking the fruits as he needed. That, of course, seems a big sum, but allowing three-quarters of a pound of fruit to each plant, making a total of 18½ lbs., the sum is not excessive, especially for so fine a sample. Still the price quoted serves to show something of the market value of good forced Strawberries.—A.

**Grape Madresfield Court.**—It will have to be a grand Grape which will supplant the Madresfield Court, but the pity is that with some people it is addicted to cracking. The observations of "W. I." (p. 365) are opportune, as any hints bearing upon this evil of cracking cannot but be of benefit. That cracking can be prevented has been proved again and again, but the grower in any case has to be on the alert. By my employer this Grape is thought much of, therefore care is taken to prevent it in as good a condition as possible. As stated by "W. I.," fluctuations of temperature are certainly inimical to its well-doing and will surely lead to wholesale cracking. My impression is that under-thinning is also answerable in some cases for cracking. As proof of this, last season I had a few bunches which were under-thinned, and at the extreme point of the berries a little juice oozed out and decay was not long in setting in afterwards. Other bunches which had been well thinned were not injured in the least. The bunches of this Grape must undoubtedly be well thinned. I have no difficulty in colouring up the larger berries, and I never saw larger than those produced in this garden. Over-cropping and starvation are the two evils to guard against. Starvation can take place other than from the want of nourishment at the roots, and that is by keeping the viney too cold and draughty. The hints given by "W. I." to prevent cracking I fully agree with.—A. YOUNG.

**Two good early Nectarines.**—Out of all the many excellent exhibits at the great show held at the Inner Temple Gardens none were so interesting to fruit growers as the remarkably fine collection of Nectarine trees staged by Messrs. T. Rivers and Son, Sawbridgeworth. The feature of this exhibit was the very prolific habit of the trees and the large size and deep rich colour of the fruit. So far as I could see, only two varieties were staged, viz., Early Rivers and Cardinal. The former I have known for a year or two. Unlike some of the early class of Peaches and Nectarines, there is no bud-casting, with its attendant loss of crop and disfigurement of the trees by long stretches of bare wood. Cardinal is stated to be fully equal to Early Rivers in every respect, and, judging from the trees staged, it is worthy of a place in every garden where early Nectarines are required. Messrs. Rivers and Son's representative informed the writer that the trees shown were not started until after Christmas, and ever since the time of starting they had been grown in a comparatively cool house that had only two rows of pipes in, *i.e.*, a flow and return. I think this speaks volumes for the value of the two varieties, as, after many years' experience of early forcing, I have never found any sorts that would produce similar results in the time. When we ca

grow varieties that will bear fruit about the middle of May with moderate forcing from the end of December, it means a considerable reduction of expenditure in fire, labour, &c., to the market grower, to say nothing of the boon they are to the gardener in a private establishment. Another feature of both Early Rivers and Cardinal was that the fruit in the most shaded parts of the trees was equally as well coloured as that exposed to the sun. Many fruits were on bottom branches, heavily shaded by overhanging shoots, but, in spite of the unfavourable situation, the colour was perfect. The flavour of Cardinal is very good indeed, somewhat resembling Pine-apple with a dash of Stanwick intermixed, and is deliciously refreshing.—W. G. C.

#### GRAPE BLACK HAMBURGH.

UNDOUBTEDLY, as "W. G. C." (p. 346) points out, this is the most popular Grape, and it is, indeed, quite indispensable, because from the time when the winter-kept Grapes are gone until autumn comes again there is no other variety so largely used. I cannot boast such a lengthened experience as "W. G. C.," for he says such grand examples as were exhibited twenty years ago are seldom, if ever, equalled now, which would naturally imply that he had matured experience at the time of which he writes. I am inclined to think, however, that a good memory must be in evidence to be able to say that the Grape in question has deteriorated to such an extent as that described. During the last twenty years great changes have been brought to bear on Grape growing, and certainly I had thought that the growers of the present day were equal to those of twenty or more years ago, whether it appertained to Black Hamburg or any other variety. I know there are records of some exceptionally large bunches having been grown, but I fully expect in some instances there were local influences apart from the general cultivation to account for such extraordinary bunches.

Although the modern lightly-built vinery may not be so favourable for the Black Hamburg Vine as that with more wood and less glass, some exceptionally fine Grapes are still grown and exhibited, and I have sufficient confidence in the present generation of Grape growers to think that quite as good are produced now both in point of bunch, berry, colour, and bloom as those known to "W. G. C." twenty years ago. In my own district is a garden that many years since had a fame for large bunches of Black Hamburg. Since that time the old structures have been swept away, and more modern ones erected in their place, and first-class Grapes are grown now as then.

As an exhibition Grape it may not be grown so largely as it used to be, because there are other varieties in the field. Madresfield Court is a great favourite both among exhibitors and judges at the summer shows, and if this is staged in its best form, it is seldom that it is beaten by Black Hamburg. Gros Maroc, too, comes into competition, having such fine berries and of a jet-black colour. For quality of course it cannot compare with the variety in question, and it is not reliable in bunch, at least not generally, as with many it has a fault in coming small. At late summer exhibitions Alicante often figures largely and well, and I think it quite possible that the appearance of these varieties in competition with Black Hamburg has led "W. G. C." to assume that it has lost some of its old form and grandeur.

Colour is so often the determining point with judges at summer shows, that Madresfield Court, Gros Maroc, and Black Alicante get the most

favour; the Hamburg, owing to its not retaining its colour long after it is fully ripe, being often placed in an unfavourable position. It does not matter what value the Black Hamburg may have possessed a month previous to any exhibition, if it has to be staged among well-coloured Alicante, Madresfield Court, or Gros Maroc it must naturally be seen at a great disadvantage, when its colour is going off. Presented in its highest perfection, Black Hamburg is beaten only by accident by the other sorts named.

On the old system of growing these Grapes "W. G. C." says the borders were made of sound fibrous loam and lime rubble, and very little manure beyond a mulch from the farmyard every spring. How many an old Vine border has been the grave of dead horses and other animals, those who had them so buried evidently believing that great virtue was obtainable from rich food other than natural manure. My experience of Vine roots is that, unless something tempting is put on or given more often than once in a season, they will not long remain in the border, but ramble away in search of fresh food in the garden. I know of many cases where Vine roots are dug up every year in the open ground away from the border, and the more heavily the soil is manured the more abundant are the roots. A hard gravel path is no barrier to them, nor is a brick wall if they are bent on a search for food. The grower who produces the best Black Hamburg Grapes, I see, each year resorts to high feeding, something of a stimulating nature being given each time the Vines are watered, and he is undoubtedly an enviable prize-winner.

WILTSHIRE GARDENER.

**Fruit prospects in South Devon.**—While looking over a plantation of young Apple trees on the Paradise stock the other day I made a few notes as to the prospect for fruit given by the different varieties. Bismarck, Duchess of Oldenburg and Cellini are in profuse bloom. Lord Suffield, Potts' Seedling, Ecklinville Seedling, and Lord Derby are good, while Cox's Pomona, Lane's Prince Albert and Warner's King are fair. Beauty of Bath, Peasgood's Nonsuch, Dumelow's Seedling, King of the Pippins, Red Astrachan and Worcester Pearmain are very scanty. Lady Sudeley, Blenheim Orange and Lord Grosvenor have no bloom. The soil in this instance is heavy and retentive and most of these young trees bore well and had to be severely thinned last year.—S. W. F., *Torquay*.

**Bowood Muscat and other Grapes.**—I am greatly obliged to Mr. Crawford for his "correction," but really it was the remark of Mr. Crawford which prompted me to send notes of observation on this Grape. It must have been in one of the other journals probably in which the article was published identifying the Grape referred to with Muscat of Alexandria. I pass my gardening papers (six in number) to the young men and have not yet examined them, but I am quite in touch with the remarks of Mr. Crawford, and perfectly sure that purchasing the Bowood as another variety is in many cases quite chimerical. Circumstances, I know, change the character of many Grapes. I remember in my earlier gardening days the altercation which took place with the late Mr. Denholm at Broommouth, East Lothian, and a number of experts, who could not accept his monstrous Muscat of Alexandria as being the real old favourite. I did not; but certainly did not believe it was the old third-rate sort, White Tokay. Mr. Thomson (then at Archerfield) cleared the matter up, and wrote that the Grapes were a true type of Muscat of Alexandria. They were proved by inarching or grafting on Archerfield Vines, and no doubt were a triumph for Mr. Denholm, who grew berries to such a size (minus flavour) for exhibition, that

they deceived the *sarantsat* Edinburgh. I remember my late friend Mr. Cramb, at Tortworth, doing something of the same kind. I also remember Mr. Spencer's (then of Bowood) challenge to Mr. Cramb, who said that Bowood Muscat was Muscat Escholata. I have many notes on the varieties of Hamburg, which are at least four in number.—M. TEMPLE, *Carvon, N.B.*

**Good late Apples.**—The fine collection of Apples put up by Messrs. G. Bunyard and Co. at the Temple show should prove to the most sceptical that by a judicious selection of varieties we could produce Apples that would meet all demands without calling in the aid of the foreigner. The whole exhibit was very good, but amongst the varieties that were particularly fine, mostly high coloured, and remarkably plump, I noticed Calville Rouge, a variety that has kept sound with me for several years into August; Wagener, a nice large red Apple; Calville Malingre, well coloured, and of fair size. Newtown Wonder was especially noticeable for its handsome colour and shape, also looking as fresh as if just plucked from the tree. King of Tompkins County evidently succeeds better with Mr. Bunyard than with me in Herefordshire, never having had it so good in appearance as the dish staged. Alfriston had kept very sound and well; also the Melon Apple, which is an excellent late dessert Apple worthy of a wall in cold districts. Tibbett's Pearmain was in prime condition, and is a dessert variety that I believe will be more grown as its merits for late work become more fully known. Striped Beaufin and Annie Elizabeth were excellent, particularly the former. Ribston Pippin is seldom so plump and fresh towards the end of May as in Mr. Bunyard's collection. High Canons was also fine, with many others. Another grand late variety that I did not observe staged was Lane's Prince Albert, but possibly this was an oversight on my part.—W. G. C.

#### KITCHEN GARDEN.

##### VEGETABLES AT SYON HOUSE.

Those who read the reports of the meetings of the Royal Horticultural Society will not need to be told that Mr. G. Wythes, gardener at Syon House, Brentford, figures very frequently as a successful exhibitor of vegetables. If any or all of these various exhibits had been specially prepared for exhibition there would have been less room for congratulation. As it happens, nothing of the sort is attempted, and all that has been exhibited I can very well believe were simply some of the best of what is grown on an extensive scale to meet the demands of a large establishment. During the prevalence of the severe frosts last winter and for many weeks, or up to the present time, fresh vegetables have been very scarce indeed, but, judging from what I saw recently at Syon, the scarcity has not been much felt there. Nowhere else have I seen such grand beds of spring Cabbage. In one breadth there were 2000 plants to be seen, all of which had stood through the winter, and would form a close succession to another still earlier batch that had been cut from since April 9. The varieties that have done such good service are Ellam's Dwarf Spring and Veitch's Matchless, the latter not greatly differing from Ellam's. Mr. Wythes makes two sowings, the first on or about July 10 and the second about ten days later. The earliest raised plants, although a great success this season, are not depended upon so much as those raised later, and which are planted the most extensively accordingly. All are planted in succession to Onions without any preparation of the ground beyond cleaning, and this firmness of root-run is the salvation of the plants, as it invariably promotes a sturdy growth, neat hearts, and but few outside leaves also resulting. The plants are disposed 12 inches asunder in rows 18 inches apart—a very different arrangement to that favoured by the old school of gardeners.

Spinach, again, passed through the winter comparatively uninjured, and although large quantities were gathered almost daily from the time milder weather set in, many sacks of it were growing to waste when I was at Syon. Mr. Wythes has been a consistent advocate of the merits of the variety *Victoria*, and there is no mistaking its superiority over the older and much smaller-leaved forms. The first sowing of winter Spinach is usually made on or about August 10, a second sowing not being made till five or six weeks later. Well-prepared ground is devoted to these important crops. Late autumn and successional gatherings are made from the earliest breadths whenever the weather is sufficiently open, but the later sowings are not available till the spring. More seed was sown during the first week in March and the plants duly thinned out. Such a grand lot of great succulent leaves as were to be seen during the third week in May would have convinced anyone of the immense superiority of the *Victoria* over the older forms of Spinach.

Very few gardeners can claim to have cut many Broccoli this year, but Mr. Wythes had a good supply at Syon, several hundred plants having been saved. It must not be thought that Syon Gardens enjoy any great immunity from frosts; sheltered they are to a certain extent, but seeing that they are only a short distance from the Thames and are nearly surrounded by other water, they would appear to be more than ordinarily liable to suffer from frosts. The Broccoli saved were principally Veitch's *Medel* and *Cattell's Eclipse*, though both well tried hardy varieties would probably have succumbed to the frosts had they not been heeled over or laid. During the second week in December trenches were opened on the north side of the plants, and these were then heeled over, the soil from the next trench being banked well up to the leaves, so as to effectually protect the most vital part of the plants, viz., the stems. The work was done in no half-hearted manner, and this, coupled with the late date of carrying it out, made it next to impossible for the heads to draw up again. Large hearts were not had, nor are they desirable at any time. Even if they were it would yet be conceded that small hearts are better than none at all. Cauliflowers would follow closely upon Broccoli. The condition of the Cauliflower plants fairly surprised me. A south border was filled with about 1300 plants, many of them forward enough to be cut from before the end of May. The varieties preferred are *Dwarf Erfurt* for the earliest supplies and *Walcheren*, the latter proving superior to *Early London*. Seed was sown on or about August 15, and the plants resulting wintered in handlights and rough frames. No coddling or undue protection is afforded, and, as a consequence, the plants are this season sufficiently hardy to move into the open border during the second week in March. They are found to move best out of 3-inch pots. In addition to well manuring the ground for this crop, guano is also freely washed down to the roots after active root and top growth has well commenced.

Kidney Beans are in great demand at Syon nearly or quite all the year round, and in order to relieve the forcing houses and pits of the strain upon them, as well as to save labour, open-air culture, or what may be termed such, is started upon as early as may be attempted with a reasonable prospect of success. A selection of the old *Mohawk* is mostly relied upon, another old favourite with me, *Syon House*, also being grown. The seed is sown thinly in 3-inch pots during the first week in April, and placed in cold frames rather than heated structures to germinate, while the plants are further kept as hardy as possible. When strong enough and before becoming much root-bound they are planted out on what were formerly outside Vine borders, and roughly protected with frame-lights and hand-lights. By the end of May the first gatherings would have been made. Extra pains are also taken in forwarding *Broad Beans*. In this instance Veitch's *Early Longpod* is sown in boxes late in February and

placed in cold frames, and the plants resulting kept hardy. They were duly planted out, quite in the open, thinly in rows 2 feet apart, and when I saw them on May 20 pods were setting freely, gathering taking place presumably nine days later. *Early Peas* were in an equally promising condition. The varieties favoured are *Chelsea Gem* for the earliest, with *Stratagem* and *Duke of Albany* to afford a good succession. All were sown at the same time, or about the first week in February, in 5-inch pots and placed in cold frames. They were planted out on warm borders during the third week in March, or later than usual, and the crops were, as a matter of course, also later, as there would not be many pods fit to pick before the end of May. *Duke of Albany* when about 2 feet high is frequently topped, this causing it to branch freely, and, as treated by Mr. Wythes, is unrecognisable, but the plan is evidently a good one, as it promotes early cropping and does away with the necessity for using tall stakes.

Lettuces were abundant and good. The varieties *Golden Queen* and *Early Paris Market* sown in boxes and the plants duly put out on warm beds and borders heart in surprisingly quickly. *Perfect Gem*, another popular Cabbage Lettuce, giving a capital succession. Turnip-rooted Beet is also raised in boxes, and the plants dibbled out at the foot of a south wall and other sheltered positions. The seed was sown during the first week in March, and three months from that date the roots would be quite large enough for use. As it happens, Mr. Wythes has abundance of old roots of the *Cheltenham Green-top Beet*, and these are comparatively fresh, richly coloured, tender, and sweet—second to none, in fact. The white and purple-topped *Early Milan Turnips* sown on a warm border the last week in February or early in March were large enough to pull when I saw them, and the same varieties grown in frames had been in use for six weeks previously. Potatoes *Early May* and *Veitch's Ashleaf* were very forward among fruit trees in borders, and the first named, together with *Sharpe's Victor*, are the favourites for frame culture. Asparagus is largely forced in frames, and a grand supply, commencing late in February and continuing till unprotected beds are productive, was had, as usual, from protected and gently forced beds. These latter are permanent, and have been in existence thirty years. They have pigeon-holed sides; the pits between are filled with leaves, and shutters are used for protection. The plants are kept in a very vigorous state by means of fish manure and abundance of water and liquid manure. Seakale is grown next to these beds, and the half rotten leaves from the pits are utilised for blanching the tops of the unforced portions.

Globe Artichokes are far from being hardy at Syon, but Mr. Wythes knowing this is never caught napping. It is his practice to winter a number of rooted offsets in frames and plant out early in the spring. It is worthy of note that *Turnips Yellow Malta*, *Petrowski* or *Finland*, and *Chirk Castle Blackstone* stood well where grown, and were in good condition for table use after the frosts left the ground. Of winter green vegetables the hardiest were *Brussels Sprouts*, *dwarf Scotch Borecole*, *Asparagus*, and *Cottagers' Kale*, and late raised plants of *Read's Hearting Borecole*. Mr. Wythes has succeeded in effecting a cross between *Asparagus Kale* and the old *Ragged Jack*, and a good breadth of this distinct novelty will be planted this season. Judging from the extraordinary number of plants in seed beds or already planted out, there is little likelihood of a scarcity of vegetables being experienced at Syon next winter, and altogether it is doubtful if a better managed garden can be found anywhere.

W. INGULDEN.

**Late Potatoes.**—In the majority of cases these will now be through the ground, and, taking advantage of the bright weather, the plots should be hoed through and all weeds killed in their infancy. Those only who are short of labour know the value of taking such work in hand in

the nick of time. If weeds are allowed any grace and the weather should set in rainy, it is often with difficulty that Chickweed and other rapid spreading weeds are eradicated; consequently the Potatoes do not get a fair start. The admission also of sun and air into the surface works wonders amongst Potato crops. Where the soil is shallow and poor, and manure was not over plentifully supplied when the ground was dug, the present time is opportune for giving a liberal broadcast sowing of some good artificial manure. This will wash in with the first rain and prove of great value. Crops grown in fields for winter and spring supply must be similarly treated if the best results are expected. The horse hoe must be put between the rows, and that portion of the ground nearest the Potato haulm which this implement cannot touch cleaned afterwards by the aid of hand hoes. It must be borne in mind that in field culture clearing the ground from weeds as soon as the growth peeps through and subsequent frequent surface stirrings are of as much value as manure.—N.

**Open-air Tomatoes.**—By this term I do not mean plants having the advantage of a wall, but those on open quarters. The middle of June will be the best date for the final planting of this batch, which should consist of the more hardy varieties recommended some time back. If the plants are not thoroughly hardened, it will be wise to keep them in the shelter of the frame-yard for another week, feeding them a little if the pots are full of roots. Do not add a lot of rich farmyard manure to the ground they are to occupy, as, independent of encouraging disease, plants so treated often run off into strong, long-jointed growth and fail to set any fruit until late in the season. A sheltered piece of ground from which early Peas have been cleared will answer well, nor is it advisable to again dig it, a firm root-run being conducive to a moderately slow growth and final fruitfulness. After planting, leave a shallow basin round each stem, so that water will find its way through the ball, and support each plant by a stout stake. As growth advances, remove all side laterals, pinching the main shoot out when the summit of the supports has been reached. Where the soil is shallow and very warm, a mulch later on will aid in retaining root moisture, but this should not be laid on very thickly.—C. N.

**Protecting early vegetables.**—I have never proved the advantage of temporary shelter amongst transplanted batches of spring-raised Cabbages, Cauliflowers, Broad Beans and Cos Lettuces more thoroughly than this season. I always sow some of the foregoing in the early Carrot frame, and this year they grew so fast, that they were ready for planting out, so far as size was concerned, before the Carrots could be exposed by removing the light in the daytime. They were put out in March on open quarters and thickly screened by Yew boughs, and although cold cutting winds prevailed for weeks together at that date in this district, the plants have done well, and will well repay the extra trouble bestowed on them. Many ignore this coddling, as they call it, but when their plants are ruined from exposure they find to their sorrow that the trouble of raising and establishing secondary batches, and of pushing them on to atone as much as possible for lost time, far outdistances that which would have been necessary in the first instance. Our garden lies rather high, and not being over well sheltered, catches much of the cold spring wind; hence the great necessity for screening early vegetable crops.—C. H.

**French Beans.**—Sometimes in large gardens no more dwarf Beans are sown after the second lot of *Scarlet Runners* is in the ground. This is a mistake, as, unless many rows of the runner type are grown, there is liable to be a break in the Bean supply owing to very close pickings. If a small batch of the French type is sown every three weeks, duly thinned and occasionally watered, they will, if old pods are not allowed to accumulate, yield over a long period. Any out-

of-the-way corner or nook may be utilised by the dwarfs, and the best plan is to sow each time two or even three sorts, as no two varieties come into yield exactly together. Canadian Wonder, Negro Longpod, and Webb's Victoria, the last a most valuable Bean on account of its freeness in bearing, dark colour, and good flavour, are all suitable for this time of year.—J. C.

**Successional Runner Beans.**—About the end of the second week in June is a capital time to sow Veitch's Mammoth Scarlet Runner, a fine variety that stands drought well. Except on deep rich soils, the best plan with this sowing is to take out trenches of fair depth, and after laying in the bottom a good thickness of decayed manure, to return the soil to within 2 inches or 3 inches of the top. This will support growth and lessen the necessity of so much watering should hot, dry weather ensue. As it is not everyone that has an unlimited supply of very tall stakes, this sowing may be supported with ordinary Pea rods and the tops pinched. This will cause a more branching habit of growth and a plentiful supply of pods. Give plenty of room between the rows, and sow more thinly than for the earlier crop, as most of the seed will germinate and the ground will not then have to be loosened by pulling out the overplus seedlings.

**Peas and hawfinches.**—Just at this season many gardeners are troubled by hawfinches attacking their early and second early Peas. Those who do not know the bird often blame the sparrow for all the mischief, but, bad as the latter bird is, the destruction he works amongst rows of Peas is comparatively nothing to that of the hawfinch. This bird is in size between a sparrow and a thrush, of handsome mixed plumage and possessed of a powerful bill. A brace of birds will sometimes in the course of a couple of days entirely ruin a good row of Peas. They make their principal raids in early morning, and again just before dusk, their presence being detected by their shrill note. I have caught as many as ten in one season in small iron traps baited with a Pea and sunk in the ground, the bridge of the trap being covered with fine soil. I have frequently had to net my earliest Peas against the hawfinch, and am afraid I shall have to do so this season. It is well where a gun can be used, as the birds do not like the sound of firearms.—J. CRAWFORD.

**Early Cabbages.**—With the finish up of white Broccoli comes a period of scarcity in hardy vegetables that has been largely accentuated by the hard winter. Just now the markets and shops are very bare of any cheap forms of greens; indeed, the barrenness seems to be almost unusually so. Spinach is fairly plentiful, but it never can be a common vegetable, as not only does its leafage under cooking shrink so much, but its taste is far from being acceptable to the bulk of vegetable consumers. Asparagus is plentiful for such a vegetable, but the price (1s. 6d. to 1s. 9d. per bundle) renders its acquisition by the people generally impossible. We have more need than ever now of some undoubtedly hardy early-heating Cabbages. These can generally be found in private gardens where good stocks of Ellam's Early, Early Gem, Early York, &c., are grown, but market growers who have to cater for the million seem still to adhere to the larger hearting and later sorts; hence when, as now, a period of barrenness comes there is in the fields nothing better to eat than mere half-grown Cabbages. Of what use is it to cry about foreign importations when we have now, at the end of May, nothing better to offer the public than such poor material as this?—A. D.

**Notes on Asparagus.**—I was glad to see Mr. Kemp's notes on Asparagus, and especially his objections to narrow raised beds. I never yet met with good Asparagus produced over a series of years from narrow raised beds. It may succeed for the first few years, but afterwards the produce is very scanty. I cannot see how it can be otherwise, the rooting and feeding space being so cramped. The filling up of the alleys with rich

feeding material is a course of treatment which I have had occasion to recommend several times in the pages of THE GARDEN. The bed here is not mulched in the autumn, but otherwise it is treated similarly to Mr. Kemp's. Wood ashes is a capital material for Asparagus. I dress the beds over with this and well-rotted manure in the spring before growth commences, and the result is that the whole surface is a mass of roots. The shoots rise up strong, and the quantity gathered from a given area would surprise many people. Soot, salt and guano I use for the occasional spring and early summer dressings. As a rule, Asparagus roots are too deep, and the soil not open or rich enough for their well-being. Very late cutting is also injurious.—A. YOUNG, *Abberley Hall*.

## GARDEN FLORA.

### PLATE 1017.

#### LUPINS.

(WITH A COLOURED PLATE OF TREE LUPIN.\*)

BROADLY speaking, the genus above named may be divided into three groups, viz., annuals,

*The Tree Lupin (Lupinus arboreus).*

perennials, and those of a sub-shrubby or arborescent character, each alike valuable. The number of species met with under cultivation in gardens is comparatively few, those most frequently seen being either annuals or perennials. Taking them all in all, not only are they a beautiful and interesting, not to say useful, group of plants, but they are all of them of very easy cultivation in any good ordinary garden soil. Especially beautiful and varied are the numerous varieties of annuals which may briefly be described as among the most ornamental of summer-flowering plants. These may be sown in the open ground in March

\* Drawn for THE GARDEN at Gravetye Manor by A. F. Hayward, June 14, 1894. Lithographed and printed by Guillaume Severeyns.

or April, or in successional batches in both months, where they are intended to flower, or they may be sown thinly in pots and transplanted.

The perennial kinds are also among the easiest plants to grow, and given a good depth of soil into which they may root freely, they quickly form handsome bushes. These when in flower are most effective. The perennial kinds are readily increased by division and also by seeds. When dividing the plants it will be found a good plan to pierce the prong of a small hand fork into the woody rootstock and then wrench the plants asunder. This is a safer method than using a knife for many things, the latter often causing the loss of many valuable roots. In the case of a good strain of *L. polyphyllus albus* for example, division is the only certain way of increasing it. Notwithstanding good white strains are obtainable from seed, and though the white polyphyllus may easily be distinguished by the foliage alone, there is a good deal of variation in point of purity in the flowers. It is a good plan with these late spring flowering plants to propagate them by division early the previous autumn. By so doing they gather strength before flowering time comes round. There are few herbaceous perennials capable of producing a finer effect in the garden than well-grown and equally well-flowered examples of this white Lupin. An old and common plant it may be, but one of the finest notwithstanding.

The shrubby kinds are of equally easy culture and may be increased freely by seeds or by cuttings slipped off with a heel attached in summer-time and inserted in sandy soil in a cold frame. In this way *L. arboreus* roots freely, or self-sown seedlings may be obtained in the vicinity of the old plants.

*L. ARBOREUS* (the Tree Lupin), represented in the accompanying plate, is a native of North America, from whence it came to our gardens just a little more than a century ago. The pale yellow and fragrant blossoms of the type are abundantly produced, and when the plant attains to a good size it is most effective either in the shrubbery or as an isolated specimen. When fully grown it is several feet high and often 6 feet through, while its silvery and somewhat downy leaves render it quite distinct. It is also an excellent plant against a wall having a western aspect.

The best known of the perennial kinds are

*L. POLYPHYLLUS*, a bold, free-growing perennial attaining 4 feet to 5 feet high and having handsome spikes, about 2 feet or more in length, of blue, lilac, purple, or white flowers. Raised from seeds this is a somewhat variable plant in point of colour, while *L. grandifolius* is a distinct large-leaved form of this plant, also known as *L. macrophyllus*.

*L. NOOTKAENSIS* is a plant of dwarfier and more compact habit, seldom more than 2 feet high. The predominant colour is blue, mingled with more or less intense purple, with veins of a deeper hue. A neat and showy border plant.

The above are those most frequently met with in cultivation, while such kinds as *laxiflorus*, *leucophyllus* and *sub-carnosus* deserve to be more frequently seen than now. Among the more tender kinds *L. mutabilis* is deserving of notice as worthy of cultivation.—E. J.

— The variety figured is a very fine bright coloured one, and the plant most effective when

covered with flowers. There could be no handsomer flowering shrub than this for favoured gardens, and good forms being scarce there is all the more reason to cherish and take care of them. We have raised batches of Tree Lupins from seed and not found one worthy of retention when compared with this good yellow one, the prevalent tones of colour being light slaty-purple or pale yellow in dull and ineffective shades. Any that are clear and good in colour should be increased by cuttings, which when well rooted and planted out in a sunny spot in light loamy soil soon grow into large bushes, and flower abundantly for several weeks during the early summer months.—A. H.

## THE WEEK'S WORK.

### HARDY FRUITS.

**VINES ON WALLS.**—So far, with the exception of a sudden fall in the temperature for a few days, we have had brilliant sunshine and warm nights, similar to the spring and early summer of 1893, one of the best seasons on record for open-air Grape culture. With Vines much healthier than usual, the bunches are stronger. Shoots for extension should be laid in, and those with fruit should be stopped at the second joint beyond the bunch. All laterals should be freely cut out, and in places deficient of wood a strong shoot should be reserved. Only one shoot must be left to each spur, and any lateral growth left to develop should be stopped at the sixth joint. It is well to allow the new growths intended for extension to become a little firm before nailing them to the wall, as in a tender state the shoots soon break. It is best to give a loose tie for a time, and nail back later on when the wood is matured, as it should be borne in mind the young wood of this season's growth will next year produce much finer fruit than the cut-back or spur growth. If a fair quantity of new wood can be laid in each season, there will be finer crops and early ripening is facilitated. By this system much of the old wood which produces a weak growth can be taken out when pruning. In selecting new wood get it as near the base of the tree as possible and allow plenty of room. Thinning of the bunches in the open is not sufficiently practised, but well repays the cultivator, the berries left being much finer and ripening sooner. Now is a good time to feed, as the growth being strong, liquid manure may be given freely. Failing this, guano or any other quick-acting fertiliser should be given and well washed down to the roots. When possible a good mulch will do much good. The best outside Grapes I ever saw were from Vines which had the contents of a small tank emptied on the soil every ten days during the growing season.

**INSECTS ON VINES.**—The Vine is less subject to insects in the open air than under glass, and is more readily managed if a little extra attention is paid to culture. Mildew being the worst enemy should be got rid of as soon as detected. Green and black-fly also attack the young shoots if the roots are dry or require food. Mildew is a terrible scourge, and must be removed, or loss of crop follows. One of the best remedies is sulphur dusted over the affected places, and renewed as required, as damp and rain soon destroy its power in the open. I have also found syringing with a mildew specific of great advantage, as this can be made to cover the back portions of the plant, and if used frequently will clear the enemy. In using the mixture, it is well to syringe afterwards to clear the berries of the specific, as if allowed to rest on the bunch it marks the fruit.

**PEACHES AND NECTARINES.**—Trees of these on walls will now require much attention to keep the foliage in a healthy state, as owing to the cold weather a short time back black and green-fly made their appearance, the leaves curling badly. Unless the pest is got rid of, it will cause

loss of crop and leaves also. I have found the best remedy for black-fly is Bentley's quassia extract. It is readily dissolved in cold rain water, and is far superior to the old method of soaking quassia chips, the extract being ready for use in a few moments. Thinning the fruit should now receive attention. It will be best to remove a large portion of the small fruits, giving those which have got the start every opportunity to swell. There need be no fear of any fruits on healthy trees not stoning, and if the foliage is kept clean and the roots well fed, syringing the foliage overhead in the evening, a healthy growth will follow. Mildew on a few sorts may now make its appearance, and the remedies advised for Vines apply in this case. Thinning and stopping of the shoots will also be necessary. By early stopping and removing useless wood cleansing will be facilitated. The leaders required for extension and the well-placed shoots on the upper sides of the trees should get a support, but merely to keep in position. Any nails or ties must be temporary. Shoots not required for extension and on which fruits are swelling should be stopped at a few joints from the base. In the case of young trees there is no necessity to use the knife too freely, as if the trees are allowed to cover a good space they invariably do better, are much cleaner, and time is saved. Young trees may be given more latitude than older ones, it being an easy matter to prevent grossness by fruiting freely. The ties of young trees should be frequently examined, as they soon cut into the tender bark when growing.

**CHERRIES** are cropping heavily and will need much support in the way of liquid manure and mulching when the weather is dry, these trees in light land soon suffering. I am sorry to say that during the last few days aphid has made its appearance and in quantity, the points of the leading shoots being badly attacked. There are few better remedies than quassia, and to be effectual no time must be lost, as the fruits mature so quickly. Many of the insects may be removed by pinching off lateral or any growths not wanted for extension, dipping the points of the main shoots in a solution as advised and syringing over afterwards. Thinning in many cases would be advantageous to the crop even in the case of Morellos. The wood for next season must also receive attention, and in the case of dessert varieties strong growth laid in thinly will soon make fruiting wood. Crowded spurs or breastwood should be thinned out early to allow light and sun to reach the fruit; small weakly growths should be pinched to the second or third joint and will then make short spurs. In the case of the Morello sufficient young wood must be laid in each season, the crop being borne on the young wood of the previous season. Any foreright shoots may be cut back to three or four eyes; the lower buds will then make short spurs or fruiting wood, and the longer clean shoots should be laid in full length.

**APPLES AND PEARS.**—The growths of the former on walls will need thinning if grown for specially fine fruits, the breast-wood being kept cut away and the main shoots laid in position. Pears need more attention than Apples. In many places thinning of the fruit will be necessary. Pinching and training will likewise need attention. I do not advise too early pinching, as it induces a forest of spray, but when done in season it promotes a fruitful growth. Of course it is necessary to remove useless breast-wood, as such never produces fruit buds. Rainfall in this locality having been very slight, watering will soon be a necessity in the case of young or newly-planted trees, and a good mulch will do much to keep the trees in an active, healthy state. Few materials are more suitable than stable manure, which can be used in a fresh state. Should the short material be required, the long litter will be of great benefit, retaining moisture and preventing the water running away. Cow manure in a partially decayed state, mixed with strawy litter, is a splendid mulch and provides food at the same time. In thinning the fruit take into consideration the variety, if a large or small kind. In the case

of large fruits of the Pitmaston type thin to one fruit on each spur. Newly-planted trees on walls or in the open should not be allowed to carry a crop: the blooms and newly-set fruits should be removed. With young trees early mulching is important.

**STRAWBERRIES.**—Owing to the drought I have been compelled to water the early Strawberries, as the crop, being heavy, is in need of support. There is no better time than the present to feed Strawberries, and manure either in a liquid state or in the way of a rich fertiliser as guano, well washed down to the roots afterwards with clear water, may be given freely, and will help to swell the fruits. In watering with liquid manure care should be taken to place it close to the roots, and it is much better to give a thorough soaking once a week, as merely damping the surface does little good. Late-planted Strawberries for next season's fruiting should have all flower-trusses removed as they show, also runners, and if possible be mulched with some spent manure.

G. WYTHES.

### KITCHEN GARDEN.

**EARTHING UP POTATOES.**—Batches of second early Potatoes in gardens which have not yet been earthed up should be attended to at once, and as these will have been allowed more room between the rows than the earlier short Ashleaf varieties, there will be less danger of mutilating the young rootlets with the hoe. Use moderation in earthing, as a large mound of soil only impedes the action of warmth and air and causes the tops to ripen prematurely, to say nothing of the extra labour incurred. If it is now seen that any other varieties have by accident found their way into the rows, they should be drawn out—that is to say, if any of the smaller tubers are to be saved for seed. Any rows not so far advanced may be left for another ten days before being earthed up, as it is an evil to partly bury them when insufficiently grown.

**SUMMER TURNIPS.**—The sowings of Early Milan advised in previous calendars may now be followed by sowing Snowball, Veitch's Red Globe, and for those who prefer a yellow-fleshed Turnip, Orange Jelly will be found most satisfactory. Where room is plentiful I would recommend that all the above sorts be included in this sowing, as then more of a succession will be secured; and as one is never sure about Turnips running to seed in a young state, greater security is given by such a course. Avoid south or even any extra sunny borders now, and for the rest of the season choose rather an east or north border, the same being extra well prepared by the incorporation of some rich manure, the ground being deeply tilled and firmly trodden unless heavy naturally. As before stated, manure from fowl houses is excellent for Turnips, provided always it has been well dried and powdered previously. It is bad practice to use it in a wet, raw state, especially near the surface. If in addition to that dug in a coating of it in powdered form mixed with half the quantity of soot is applied to the surface as soon as the crop is thinned, it will aid in warding off the dreaded fly, which is often most troublesome to Turnips sown now. Take care to thin early, as when left crowded they get drawn, and the base of the bulb becoming exposed, they never do so well. From 1 foot to 15 inches apart is not too much for summer crops of the more robust growing varieties. Dusting overhead immediately thinning has been completed with wood ashes will often prevent the fly from attacking the tender seedlings, and if this can be done they soon grow out of harm's way.

**BRUSSELS SPROUTS—MAIN CROP.**—The few rows of extra early plants for a supply in September and October planted some time ago are now growing away fast, the screens having been taken away, as they are now able to take care of themselves. The main batch for November and December may now be got out as soon as possible. Draw out fairly deep drills on medium and light

soils, reducing their depth, or even planting on the level where the situation is low or the soil very retentive, plant carefully with a trowel in preference to a dibber, and water home. If the weather continue dry, the watering may be repeated in ten days' time. Where an extra sowing for later work has not been made, the smaller plants from the main-crop beds may be pricked out on to a bed of rich soil in any convenient spot, and planted three weeks hence for supplying useful sprouts during the early spring months.

**UTILISING CELERY RIDGES.**—In most gardens these will all now be prepared. It is a great gain to get the trenches thrown out in good time, as the ridges can be utilised for such quick-growing crops as Lettuce, Spinach, and the dwarf early hearting kinds of Cabbage where room is scarce. I have on Celery ridges often grown Walcheren Cauliflower for cutting in August. Whatever is planted on the ridges must be well looked after as regards water. I sometimes sow Lettuces on the ridges, and thin the seedlings out to a growing distance, thus saving the labour of transplanting. Especially is this an advantage in hot weather when transplanted crops need so much artificial watering. Thinning out must, however, in such cases be done at a very early stage.

**SUCCESSIONAL CAULIFLOWERS.**—When once the autumn-planted hard-light batches of this vegetable commence to turn in they generally do so with a glut, although some varieties are certainly better for coming on gradually than others. I find Walcheren unsurpassed for turning in piecemeal, even better than the small forcing kinds which are now so largely grown. The spring batches planted out from frames or raised in heat in January and the early part of February will also be close on the heels of the above named, so that where a constant succession of Cauliflowers is required frequent sowings will be imperative. Pearl and Walcheren, recommended to be sown in March along with the first batch of winter stuff, will now be quite ready for transplanting. If on the dry side, soak the drills the night previous to planting. Sow also now the same two sorts in a cool place for following those just planted. If the two sorts are sown together, one is more certain of success, and if both do well a succession is ensured.

**AUTUMN GIANT CAULIFLOWER.**—I recommended a little seed of this popular Cauliflower to be sown in March, and where this was done the plants will be fit for putting out on the final quarters. Any of the smaller seedlings may be pricked out on to a bed well enriched with manure, planting these out in three weeks' time. If a little seed was also sown in April, the plants will be useful for putting out in June for carrying on the supply right on to the frosty weather, the plants being laid where frost will not reach them. Autumn Giant being a robust grower, thorough preparation of the ground is necessary. Plenty of room must be given, and if shallow trenches can be taken out, so much the better, as then feeding to any extent can be more easily performed. J. CRAWFORD.

**The Temple Chrysanthemums.**—I have only just seen THE GARDEN for May 18, in which a notice appears, stating that in future the annual exhibitions of Chrysanthemums in the Temple Gardens will be discontinued. These exhibitions have now been held for so many years, and in the early days did so much to popularise the flower, that I am sure I only echo the feelings of many a lover of this famous autumn favourite in expressing regret that such a determination should have been come to. Some years have elapsed since the Chrysanthemum show in the Middle Temple Gardens was abolished, and now it appears that the Inner Temple authorities intend to do likewise. It would be interesting to know exactly how many years Chrysanthemums have been grown and exhibited in the Temple; it must be at least forty, if not more. Mr. Samuel Broome published the first edition of his "Culture of the Chrysanthemum as practised in the Temple Gardens" in 1857, and had then been in the posi-

tion of gardener there for twenty-five years. But he does not tell us how long out of that time he had been growing and showing the Chrysanthemum to the public. In a list of varieties at the end of that work, comprising large-flowered, large Anemones, Pompons and Pompon Anemones, which number about 340 varieties and which were then in cultivation by Mr. Broome, a few are still, or were recently grown by cultivators of the present day. In particular may be mentioned Aimée Ferrière, Alfred Salter, Annie Salter, Beauty, Chevalier Domage, Christine, Cloth of Gold, Golden Queen of England, Leon Leguay, Nonpareil, Phidias, Queen of England, Temple of Solomon, Fleur de Marie, Georges Sand, Chick, King of Anemones, &c.—CHRYSANTH.

## STOVE AND GREENHOUSE.

### CYCLAMEN CULTURE.

This popular and most useful winter-flowering plant is very often indifferently grown. The most fertile causes of failure are over-potting, insufficient drainage, a non-porous soil, cold draughts, exposure of the foliage to the sun or allowing it to become infested with thrips. Although I cannot claim to have had an unchequered success in growing Cyclamens, yet as my plants generally do well, a few notes as to the mode of treatment may prove useful. I may here say that I do not rely upon old bulbs, as I have never had much success with these. I raise a fresh batch of seedlings every autumn, casting the same away after flowering is over. I sow the seed in August in pans, using a compost of light fibrous loam, passed through not too fine a sieve, to which is added one-fourth of leaf-mould quite free from pieces of wood. This freedom is very essential, as the sticks often engender fungus, which is ruinous to the roots of the Cyclamen. Sufficient silver sand to keep the compost open is likewise added. This is pressed firmly into the pans, which are well drained, and the seed after being sown on a level surface is nicely covered with the compost, this again being made firm. The pans are then placed either in the Cucumber house or Pine stove on a warm moist bottom, not necessarily near the glass, and shaded until the seedlings appear. Great care is needed in moistening the soil, also much patience, as germination is sometimes very slow. By the time the plants are up the weather has become much cooler and the pan is elevated close to the roof glass and no shading used. Through November, December and January from 55° to 60° is the average heat during the night which suits the plants and induces a free and healthy growth. About the middle of February potting is performed, using the same compost as before, only in a much rougher state, placing each bulb in a 3-inch pot and allowing it to remain partly above the soil. Some advocate burying it, but the plan is ruinous, as the least excess of water is apt to rot the young leaves issuing from the crown.

Potting completed, the plants are elevated as before on slates surfaced with Moss, this material holding the moisture about the pots. Shading is necessary for ten days, and gentle syringings each morning and afternoon. In watering, the spout of the can should be placed close to the rims of the pots, as if held aloof and the water dashed into the soil, the plants soon become sickly. Of the two evils, over-dryness and over-wetness, the former is the safer at this stage. The plants being subject to thrips, a slight fumigation generally is advisable as a preventive, as this pest soon plays

sad havoc with Cyclamens. Towards the end of March, the Pine stove or Cucumber house becoming too hot for their welfare, they are removed into a span-roofed Peach house and arranged on a brick slab, partially shaded by the foliage of the Peach trees, the night temperature being about 55°, rising considerably from sun heat, especially when closed early in the afternoon. By the beginning of May the small pots are filled with roots and the plants are removed into their flowering pots, these being 4½ inches in diameter. Firm, but not hard potting is necessary. The plants, standing on a brick kerb of the Peach border, are a good distance from the ventilators, and thus escape draught, which soon distresses the foliage and checks the plants. By the middle of August, the Peach house having to be thrown open day and night—the fruit being ripe—the Cyclamens are removed to a frame and stood on a hard ash bottom, the glass being slightly shaded with whitening until September, when it is removed and the plants entirely exposed to the sun. I do not care for the plan of keeping the lights tilted up all night, but close them about 4 p.m., slightly syringing the foliage. At the commencement of October the plants are removed to a light greenhouse, placed near the glass, and when the blooms are throwing up, a little stimulant is given, weak farmyard liquid being the best. Until this date I am opposed to giving manure water, as the roots of Cyclamens are very delicate and easily injured.

J. CRAWFORD.

**Iris hispanica in pots.**—It is a wonder this pretty Iris is not more generally cultivated in pots, as the flowers are valuable just now for cutting. I usually order the bulbs in August, and as soon as they come to hand I place five in a 4½-inch pot in a mixture of loam, leaf-soil and sand, and stand in a Carnation house or cool greenhouse. If the soil is in a moist state when potting do not give any water until signs of growth appear. If carefully watered through the winter the bulbs will make strong growth and throw up a flower-spike towards the end of April. If wanted in bloom earlier they will not resent a gentle forcing.—F. C.

**Boronia serrulata.**—Two or three years ago this Boronia was very difficult to obtain, but a group of healthy little specimens profusely laden with bloom at the recent Temple show showed that the exhibitors (Messrs. Balchin, of Hassocks) are as successful in the culture of this as in the case of the blue Leschenaultia. Boronia serrulata is of rather low growth, the slender and somewhat spreading shoots being clothed with curious trapeziform leaves serrated in front. The flowers, which are borne in great profusion, are of a pleasing shade of bright rose. This Boronia, which is a native of New South Wales, was introduced into this country in 1816. Taken altogether, the Boronias are certainly a very pleasing class of plants whose flowering season is spread over a lengthened period, for quite early in the year the sober-tinted, but deliciously fragrant blossoms of *B. megastigma* fill the greenhouse with their perfume; after which comes the newer *B. heterophylla*, whose rosy carmine coloured blossoms are borne in such profusion, that the entire plant is quite a mass of flower. If the foliage of this is agitated, the scent therefrom is decidedly unpleasant. The pink blossoms of *B. pinnata* are very pretty, but they are rarely seen. *B. elatior* is a decidedly ornamental member of the genus and one of the latest to flower, in addition to which it is more easily grown than some of them. It forms a freely-branched bush somewhat upright in habit, clothed with bright green pinnate leaves, and with drooping rosy red flowers. All the Boronias, being natives of Australia, require greenhouse treatment and a soil principally composed of sandy peat, to which some cultivators add a little fibrous loam. Thorough drainage is

essential, and, in common with most other hard-wooded plants, the watering needs to be carefully done. Cuttings are not at all difficult to root, but especial pains are needed to ensure a good bushy style of growth, for unless care is taken in this respect the young plants are very apt to run up thin and naked at the base, particularly *B. elatior* and *B. megastigma*. To counteract this tendency as far as possible, the young plants must be stopped freely during their earlier stages, and a free circulation of air is essential.—T.

**Correa cardinalis.**—Among the hard-wooded subjects known generally as New Holland plants that are flowering just now this *Correa* is particularly noticeable, as the blossoms are not only brighter in colour, but in other respects it differs widely from any of its associates. It is a plant that many fail to grow in a satisfactory manner, yet in Messrs. Low's nursery at the present time numerous little bushes in pots only 5 inches in diameter, and profusely laden with bloom, are now at their best. This *Correa* needs a soil principally composed of peat and sand, to which a little good loam may with advantage in some cases be added. To encourage a bushy habit of growth it needs to be stopped freely during its earlier stages. The flower of this is tubular, a little more than an inch in length, and of a bright scarlet colour tipped with green. There are certainly signs that the old-fashioned hard-wooded plants are slowly becoming more popular.—H. P.

**Market Heaths.**—Although Cape Heaths, especially those that bloom at this season of the year, are but little grown in private gardens at the present time, some have remained in favour as market plants. Prominent among them is *Cavendishi*, one of the finest spring-flowering plants in cultivation. Very nicely grown little specimens of it in 4½-inch and 6-inch pots are being offered in Covent Garden. The charming little *ventricosa coccinea* minor is also a favourite. It is wonderfully free-flowering, very compact in growth, and one of the neatest-habited members of the family. *Ventricosa superba* and *grandiflora* are also grown to a limited extent, and *perspicua nana* is still in favour. Another favourite kind is *candidissima*, an effective white-flowered *Erica* now coming into bloom. It is of easier culture than the preceding, and does not require so long a period to bring to marketable dimensions.—J. C. B.

#### BLANDFORDIAS.

I SUCCEED best with the different *Blandfordias* when grown in a mixture of peat and loam, with a liberal amount of silver sand. They are grown in a greenhouse just shaded during the hottest part of the day, and at no period of the year are they allowed to become dry; indeed they get pretty much the same treatment as a *Pelargonium*. By far the freest grower is *B. nobilis*, shown on the upper part of the coloured plate in the issue of May 18, and the roots of this being of a more fibrous nature than those of the *flammea* section, it can be increased far more readily by means of division, for the larger flowered forms, and especially princeps, need particular care to be taken in dividing an established plant. *B. nobilis* can be depended upon to flower well year after year, and as a rule the blossoms of this are the first to expand of the different species. A very suitable time for repotting or for dividing the plants if it is intended to do so is directly after flowering, for there is then ample time for them to become established before winter sets in. In dividing the thick fleshy-rooted forms such as princeps a good plan is to wash away the whole of the soil from the roots, so that they are not bruised in any way, as the least injury will often cause the entire root to decay. The dividing should be done with a sharp knife, as the two or more shoots are often at the base so close to each other, that without great care one or the other is very liable to be taken off without its due proportion of roots. In repotting these that have had all the soil washed off a very good plan is to sprinkle silver sand around the cut portion and in immediate contact with the roots. When

either established or divided plants are potted, thorough drainage should be given them, for while they are at all times impatient of stagnant moisture, yet they need a liberal supply of water during the growing season. It is a good plan to keep divided plants rather closer until the roots take hold of the new soil. Seeds are readily produced, especially if the precaution is taken to fertilise the flowers, but this should not be done unless the seeds are actually needed, as the production of seed weakens the plant very much more than if the spike were cut off directly the flowers decay. The thick wax-like texture of these *Blandfordia* flowers is a great point in their favour, for they remain fresh and bright a considerable time. Some of these *Blandfordias* are difficult to obtain from nurseries and high prices are charged for them, but one of our principal Orchid dealers who has lately devoted some attention to new and uncommon plants announces *B. grandiflora* at the relatively low price of half-a-crown. This species is unknown to me, but it is, I see, described in the "Dictionary of Gardening" as having been introduced in 1812. T.

**Staking plants.**—Though a very simple operation, this is frequently carried out in a most unsatisfactory manner, and many instances have come under my notice of late in which plants have been greatly damaged by negligent staking. These remarks do not refer to the training of specimens, but the plants in which a single stick is employed just to keep them in position. The great error that is made by many is to insert the stick but a short distance in the soil, hence the plant will in many cases have to support the stick after a time. When plants are sent from a distance this style of staking is often liable to cause great injury to them, and I have had ample opportunity of seeing the ill-effects of this in the case of many plants from different sources and sent from various parts of the country. One very pronounced case was a quantity of flowering *Carnations* in 5-inch pots, whose heavy sticks from an insufficient hold of the soil had swayed about and greatly injured many of the plants. On the other hand, a greater number sent from a long distance travelled well, each stick being inserted right to the bottom of the pot, and consequently all was made secure. By old-fashioned gardeners this was impressed upon the beginner as one of the most essential features in tying plants, but, judging by the instances that have of late come under my notice, this unsatisfactory way of staking plants seems greatly on the increase.—H. P.

#### NEW STOVE PLANTS AT THE TEMPLE SHOW.

To anyone familiar with the large masses of fine-foliaged new plants that were so prominent at the principal shows of the Royal Horticultural and Botanic Societies some fourteen years ago or more, the recent exhibition at the Temple Gardens afforded a good illustration of the vagaries of fashion, for the various *Dracenas*, *Crotons*, *Dieffenbachias*, *Aralias*, and such things were conspicuous only by their almost total absence; indeed, new stove plants of this class were contributed by only one exhibitor. Undoubtedly the best fine-foliaged stove plant was *Dracena Godsefiana*, which is totally distinct from anything else we have. Instead of one stout stem furnished regularly with foliage, thus forming a symmetrical-shaped specimen, this newer kind pushes up shoots from the base after the manner of a *Bamboo*. These shoots elongate and finally branch, thus forming a loose bush-like plant. The oval-shaped leaves, which are from 2 inches to 3 inches long, are of a deep rich green, freely spotted with creamy yellow. As far as I know there is only one other *Dracena* in this way, and that is *D. surculosa maculata*, which was introduced from Old Malabar in 1867. The leaves of this are more lanceolate in shape than those of *D. Godsefiana*, and the marking consists only of light green spots

on a dark green ground. A fine mass, too, was shown of *D. Sanderiana*, which, though not really new, is of recent introduction. This is a very pretty *Dracena*, the clear silvery variegation of which stands out very distinctly from the bright green of the rest of the leaf. The spread of the foliage is so limited that a single plant does not make much of a display, but a large mass composed of numerous stems, as shown at the Temple, forms a very striking feature. *Heliconia illustris rubricaulis*, represented by a fine specimen, has been before the public for two or three years, but it is still very scarce and commands a good price. It is the finest member of the genus, the marking being after the manner of the better-known *H. aureo striata*, but the colour is quite different. In *H. illustris rubricaulis* the ground colour of the leaf is green, with the prominent mid-rib of a beautiful shade of pink, while the veins are also marked in a similar manner. The leaf-stalks, too, are rich reddish pink. The general aspect of this *Heliconia* is that of a bold, yet somewhat dwarf-growing form of *Canna*. *Ludevica crenifolia*, a Palm-like subject allied to *Cyclanthus*, with dark green leathery leaves, is a bold decorative plant, while several forms of *Anthurium*, apparently hybrids of *A. Andreanum*, were very noticeable. The rich crimson spathes, combined with the large dark green leaves of *A. albanense*, were particularly striking. H. P.

#### BOOKS.

##### A HANDBOOK TO THE CARNIVORA.\*

IN this are comprised the members of the cat family, civets, and mongooses. It is perhaps the most interesting of the series known as "Allen's Naturalist's Library," being full of spirited accounts of the hunting of lions, tigers, and the larger and ferocious felidae. Graceful and agile, the "cat," using the term in the comprehensive sense in which it is here used, has but little in its tastes and habits to recommend it to the friendship of man, and, in fact, excepting the domesticated races, mankind could do very well without the cat tribe. In regard to external characteristics, it is perhaps not generally known that the whiskers, or vibrissae, are important organs of touch or perception. An exception to the long, cylindrical, and tapering tail of the tribe generally is found in the lion, as most observers will have probably noticed. All cats walk on their toes. The warmer parts of Asia and Africa are regarded as the headquarters of the cat family, although practically, with the exception of New Zealand, New Guinea (perhaps Celebes), the West Indian Islands (save Trinidad, regarded as part of South America), and the circum-polar regions, the distribution is cosmopolitan. In the present day Europe is fortunate in the possession of only three species—viz., the wild cat, the common lynx, and the Spanish lynx. Among other animals the nearest relations to the felidae are the civets. From a certain structural resemblance of the skull and teeth it is generally considered that the cats originated from carnivora more or less closely allied to the civets. The lion is distinguished from the majority of members of the tribe by its inability to climb. The carriage and appearance of the lion in its native haunts are said not to be imposing, and its character for magnanimity, if the term be allowed in this connection, has been doubted. The magnificence of its roar is generally conceded. In Africa lions associate in parties, comprising up to as many as ten, and a great hunter (Mr. Selous) has even seen as many as twenty-three in a party. The old idea of the lion being a clean and dainty feeder is not sustained, and it is said that it will scarcely

\* "A Handbook to the Carnivora." Part I. By Richard Lydekker, B.A., F.R.S. W. H. Allen and Co., Limited.

ever pass by the carcase of a slain animal, even though it be in an advanced state of decomposition, without stopping for a meal. Of the tiger very much has been written and said which will be found here also, but it is perhaps not generally known that at a pinch the tiger will make a meal off a snake. A tiger suddenly disturbed by a sportsman will avail itself of any loophole of escape, but—and this somewhat discounts the above statement—as the way the disturber has entered is usually the most obvious road of escape, the result is frequently disastrous to one or both. Tigers do not generally climb trees unless pressed by fear, but they have been known to clamber or even spring to a certain height where they have seen a man, and whence they thought the shot came, and pull him down. The muscular power of the tiger is enormous. The chapter on the tiger is most interesting. As regards the leopard, it is a desperate beast to hunt, as when wounded it will fight to the last, and on this account is regarded as even more dangerous than the lion. Unlike the lion and the tiger, it is essentially an arboreal animal. A favourite prey is the dog, and a traveller on a mountain path if accompanied by a dog may be surprised by the sudden dash of a leopard in pursuit of his canine companion. In India leopards not infrequently take to man-eating. The jaguar is a native of South America, as the puma is of the northern continent. Then amongst other wild things we have the marbled cat, the Tibetan tiger cat, the flat-headed cat of Borneo, the fishing cat of India, Ceylon, Burmah, South China, and thereabouts, remarkable from the great majority of its kindred by its habit of preying upon fish. In addition to fish it is known to feed largely on the large amphibious snails, known as ampullarie, which are met with in thousands in every marsh or "jhil" in Lower Bengal. How the succulent morsels are so deftly extracted from the somewhat hard shell is not known. The chapters on the ocelot of North and South America, the tiger cat of Mexico and Paraguay, the weasel-like cyra of Brazil, Guiana and Paraguay, and the Caffre cat of Africa from Egypt and Algeria to the Cape are full of interest, and with the last-named species we are brought to the cats of the Old World, beginning with the domestic cat, of which we know much less than we imagine we do, as the book clearly shows.

With regard to the introduction of domestic cats into Europe there is a considerable amount of uncertainty, and it has been asserted that the so-called cat of the ancient Greeks was really the marten. That the cat was domesticated in Europe before the Christian era, we have it on the authority of Professor Mivart. Great value was set on the cat. Towards the end of the sixth century, as is shown by the fact that in many European countries, including Wales, cat-killers were punished with what was no doubt to some a heavy fine—*i.e.*, the delinquent was required to cover the body of the animal with wheat, the tail being held up vertically, with the cat's muzzle resting on the ground. According to Jardine, no animal so soon loses its cultivation as the domestic cat and returns apparently to a state nearly wild. Then follow some curious cat stories. Cat skins are of considerable commercial importance, and the fur, which is stated to be one of the warmest, is extensively used for coat-linings, muffs, trimmings, rugs, &c. Black skins are the most valuable, and of these the best come from Holland; the very best Dutch pelts sometimes command as much as from six to eight shillings each. As is well known, the fur of the cat when rubbed is highly electrical, giving off sparks which in a dark room are easily visible. The wild cat of Europe and Northern Asia, the Pampas cat of South America, the jungle cat of India, the caracal of Africa and Asia, the Canadian lynx and the lynx family generally, with the hunting leopard of India, are all the subject of interesting chapters in this part 1, which also includes the civets and the mungoses, with some account of extinct cats. It is a work of great value and interest in a handy form. Like the rest of the series, it is full of coloured illustrations.

## TREES AND SHRUBS.

### MAGNOLIA CONSPICUA ON A HOUSE.

This fine-flowering tree of the early spring is not often seen growing on walls, but that it

The Yulan (*Magnolia conspicua*) on a house front.

may be successfully grown and flowered in this way is well shown by the accompanying engraving of a large plant in abundant blossom. *M. Soulangeana* we have also seen grown in

this way. One fine specimen on a Sussex house, having reached the top, was a glorious picture in flower, and hardly less beautiful in luxuriant leafage throughout the summer and autumn. In low-lying or unfavourable districts where late frosts are apt to occur and mar the beauty of these fine Magnolias when they are flowering, there are good reasons for giving them the benefit of wall shelter, as it may be the result of ensuring their successful blooming safe from risk of injury. Judging, too, from specimens that flower freely in the vicinity of London, such as at Gunnersbury and Syon, owners of suburban gardens who have insufficient room for planting this tree in the open might with advantage grow it against their houses. We should like to see it as popular as the *Wistaria*, which lately was flowering freely in scores of suburban gardens.

### Azalea Anthony Koster.

When this was first shown at the meeting of the Royal Horticultural Society on April 11, 1893, it received a first-class certificate and was noted in *THE GARDEN* as "one of the finest things of the meeting." After a lapse of two years this opinion is not likely to be disputed, for it has turned out to be a most beautiful Azalea, and was very conspicuous among Messrs. Veitch's exhibits at the recent Temple show. It is certainly a very fine form of *A. mollis*, having the sturdy, free-flowering character common to that kind. The flowers are large and the petals unusually broad, while their colour is very pleasing, being a brilliant orange-yellow with just a suspicion of a rose shade. It is certainly a grand Azalea either for flowering under glass or as a shrub in the open ground, where it blooms rather earlier than the bulk of the Ghent Azaleas. *A. Anthony Koster* has been spoken of as a hybrid between *A. mollis* and *A. sinensis*, but these two are usually regarded as synonymous. At all events, it is a grand garden form, and where it is intended to plant a number of hardy Azaleas this variety should be made a note of.—T.

**Tulip trees.**—Almost the only deciduous tree—so far as I have yet seen—appreciably injured by frost during the winter is the Tulip tree. There is a very lofty one, probably some 60 feet to 70 feet high, perhaps more—for it towers up above all surrounding trees in the grounds of Canbury Lodge, Kingston—which I have watched for some time past, as a long time elapsed after the usual period of foliage ere it put forth any leafage. Even now (the end of May) it has but a very miserable leaf covering; indeed, I should think two-thirds of the branches are dead. The case is not singular, as even on sand at Reigate and in a sheltered place (Woodhatch) I noticed the other day that a large Tulip tree was fully two-thirds killed. It would be interesting to learn how far other Tulip trees have been affected.—A. D.

**Xanthoceras sorbifolia.**—Although more than twenty years have passed since this plant first became known, it still remains one of the rarest of our hardy shrubs. If any doubts pre-

viously existed as to its hardiness in the neighbourhood of London at any rate, the fact of its having passed through such a winter as the past one without any injury should set them at rest. At Kew, where it is grown against a wall and also in the open without protection, it is in each case in flower. Its beauty, however, is greater in the more exposed position, the flowers being more abundant, and the handsome foliage and habit of the plant being seen to better advantage than when cramped against a wall. It is a native of North China, and its first introduction to Europe in 1868 has to be credited to the Abbé David, a name which has since become associated with the discovery and introduction of numerous Chinese plants. It is a shrub (ultimately a small tree) belonging to the Horse Chestnut family, and has handsome pinnate foliage of a bright glossy green. The leaflets are seven or nine in number, and have serrated margins. The flowers are densely packed in short racemes, 4 inches to 6 inches long, produced from the terminal buds of last year's growth. The flower is a little over 1 inch in diameter, the petals white, with a brownish red patch at the base. The species is one to be recommended to all lovers of spring flowering trees and shrubs. The generic name refers to the five yellow horn-like glands at the base of the petals.—B.

**Rhododendron blandfordiæflorum.**—This is one of the few Himalayan Rhododendrons that can be called really hardy in the home counties. Although a very distinct species compared with the common type of Rhododendron, it has not been looked upon generally as one of much value horticulturally, and it is not until one sees it growing and flowering as it does in Sir Edmund Loder's garden at Leonardslee, near Horsham, and in the neighbouring garden of Mr. F. D. Godman, that its beauty and really effective character can be fully learnt. At Mr. Godman's there is a specimen about 8 feet high and 6 feet through which a short time ago was simply covered with flowers; this is probably one of the finest specimens grown out-of-doors in this country excepting, of course, in the far south and west. The flowers as a rule are of a somewhat dull orange or cinnabar-red, and longer in proportion to their width than the flowers of ordinary Rhododendrons are. Their shape and size as well as their usually semi-drooping position render them comparable to a Lapageria. In Sir Ed. Loder's garden there is a remarkable variety in which the inside of the flower is quite a rich crimson. Two other species, Roylei and cinnabarinum, are very closely allied to this; no clearly defined lines of distinction can, in fact, be found to separate them, hence they are sunk under one name in the "Flora of British India."—W. J. B.

TREES AND SHRUBS IN IRELAND.

It has been suggested that it would be of interest to lovers of plants that some record should be kept of the effects of the unusually severe frost of last winter, and as we grow about 1100 different varieties of more or less rare plants in the gardens here, I have ventured to send you a list showing the casualties, the slightly injured and the uninjured. Among the first are several which, unfortunately, were moved just before the frost and snow set in, and it is, perhaps, hardly fair to count them among the dead, but I thought it best to give a statement of the whole.

When we read of the common Laurel having been killed in various parts of England, some people may be surprised at the number of rare and half-hardy things which have survived here, but the reason, I believe, is that the gardens lie on the slope of a hill, are well sheltered by old trees, and that the prevailing wind passes over the heads of the shrubs. In the list of survivals I have not mentioned the commoner sorts. Tea Roses have not suffered in the least, and out of some 700 plants of Pampas

Grass, about two dozen have been killed. Out of 160 varieties of conifers, the following were more or less injured: Cupressus Lawsoniana albo-spica, C. erecta viridis, C. pyramidalis argentea, C. macrocarpa, Juniperus virginiana albo-spica, P. insignis, Podocarpus andina, Sequoia sempervirens, Sequoia albo-spica, Glyptostrobus heterophyllus. This is a bad season for Rhododendrons blooming, but of Himalayan kinds, R. barbatum, R. ciliatum, R. campanulatum, R. fulgens, R. Thomsoni, R. Aucklandi, R. calophyllum, and R. niveum have flowered freely.

SHRUBS UNINJURED.

- Abelia floribunda serrata
- Acanthopanax ricinifolia
- Aciphylla Colensoi squarrosa
- Actinidia argentea Kolomikta volubilis
- Adenocarpus decorticans
- Ailantus glandulosa
- Akebia quinata
- Amorpha fruticosa
- Arbutus Rollissoni
- Aristolochia altissima
- Sipho
- Asimina triloba
- Astragalus tragacantha
- Atriplex Nuttalli Halimus
- Azara Gillesi integrifolia microphylla
- Baccharis patagonica
- Bambusa (12 varieties, all perfectly hardy)
- Benthamia fragifera
- Berberis aristata buxifolia congestifolia
- Darwini dulcis
- Jamesoni nepalensis
- Newberti stenophylla
- Thunbergi
- Bignonia grandiflora speciosa
- Broussonetia Kämpferi
- Buddleia Lindleyana
- Casalpinia japonica
- Camellias, sorts
- Caragana Chamlagu frutescens
- Carmichaelia flagelliformis
- Caryopteris mastacanthus
- Cassinia fulvida
- Cedrela sinensis
- Celastrus scandens
- Circidophyllum japonicum
- Chamerops humilis

- Bohea

J. RYAN.

The Gardens, Castlewellan, Co. Down.

**Rose Perle des Jardins.**—No yellow Rose can equal this for consistency of form, and no other kind is so continuous in its flowering. Well managed plants commencing to open their blooms in March continue to give a succession of neatly-formed flowers especially suitable for making into button-hole bouquets, &c. Mr. Axford, near Eastleigh, is a large grower of this Rose, house after house being devoted to this variety. In fact, with the exception of a batch of Catherine Mermet and some dozen or so plants of Marchal Niel, Perle des Jardins is the only Rose grown. Numerous

span-roofed houses have been built for its accommodation, each containing about three hundred plants. The plants are all grown in 7-inch and 8-inch pots, stood upon side beds of a sandy loam in rows of four plants on each side of a central pathway. The roots run through the bottom of the pots into the soil, where of course they receive much support. The pots, however, check the luxuriant growth that might otherwise be troublesome if they were planted out. Some of the plants have not been repotted or disturbed for five years. I never saw such healthy foliage. The great point which Mr. Axford observes is never to allow the air to become chilled during the night, that, he finds, being the greatest source of mildew. Every night the hot-water pipes are warmed about ten o'clock so as to maintain an equable temperature throughout the night. This practice is carried out all through the summer months, and apparently with excellent results. The plants obtain very little artificial aid; an occasional dose of liquid manure from the stable tank is all that is necessary. The plants are all grafted on the seedling Brier. Capital growth is made the first year, this being several times pinched back to lay the foundation of the future bush. The plants are hard pruned during the winter or early spring, according to the time they are required to bloom.—E. M.

### WOODLAND PATHS.

THERE is no lack of admirers of glowing beds of colour, of blossoming climber and of trim parterre, but it is seldom that the horticulturist waxes eloquent over the beauties of shady woodland ways: yet these often possess unostentatious attractions that are found wanting in the more emphatic charms of the flower garden. Very restful to the senses are those wood-paths that have been left by their originator Man to the predominant partner Nature to fashion and decorate after her own manner. She festoons with Honeysuckle, Eglantine and Bryony the boughs on which the glints of sunlight fall. In the shade she weaves the Ivy wreath. On either side the path she plants Ferns; in the lower lands the graceful Lady Fern; in the higher, the Bracken and Blechnum; while in the Fir plantations that clothe the river banks on the fringe of the moor, great fronds full 4 feet high of the Royal Fern (*Osmunda regalis*) shoot up from the peaty soil.

It is such a path, where Nature has been left undisturbed, that the illustration depicts. In the spring the wild Hyacinths and Primroses mingle their blue and yellow with the young green of the Ferns. The white-throats and blackcap warblers build hard by in the undergrowth of Hazel wands and ground Ash. The squirrel, leisurely approaching up the middle of the track, stops suddenly and, motionless, with tufted ears pricked, eyes the intruder for a good half minute until some movement of hand or foot sends him flying to the refuge of the overhanging boughs.

A blue flash through the greenery, the kingfisher threads the leafy alley on his way from the lake above, where in summer evenings the Loch Leven troutlets leap beneath the shade of the Alders, to the little stream that meanders down the valley below.

At high noon, when in the open the atmosphere palpitates with heat, the wood-way lies cool and still, the shifting rays of sunlight that filter through the Beech leaves tessellating its green carpet with an ever-varying mosaic of light and shade.

In the gloaming the fronds of the Lady Fern move aside as the young rabbits come out to play on the open spaces of the path, and in the mysterious glimmer that comes between the twilight and the dark, the white owls call

to one another from the outlying trees, while ever and anon, on silent pinions, a ghost-like form sweeps noiselessly through the dim aisles, and the dew-laden air is full of the indefinable scents of the woods. S. W. F.

### THE MARKET GARDEN.

(Continued from page 332.)

#### CUCUMBERS AND GHERKINS.

THESE are largely grown in the fields in the neighbourhood of Paris, and there is no reason

inevitably always some which are a good deal larger than this; these, however, are also utilised by the pickle-makers for another class of their products, but the more uniformly the Gherkins are of the smaller size, the better the prices which they command. Not picked, but as they are ordinarily sent to the Halle market, they fetch from 8s. 4d. to 16s. 8d. per cwt., but the small-sized pickled Gherkins will sell for 25s. per cwt. An acre of ground would produce Gherkins to the value of £32, but they are rarely grown by individual cultivators on so large a scale as this, on account of the great expense which the gathering of such an extensive crop would entail.

#### SPINACH AND SORREL.

It is not very long since Spinach and Sorrel were introduced as a catch crop in field culture in the neighbourhood of Paris, where they are generally grown on lightly-broken-up Corn stubbles. The seed is usually sown broadcast, and but little further trouble or attention is required. Some cultivators sow in drills and thin the plants out to ensure a more regular and equable growth, and they are amply repaid by having a heavier crop in consequence.

The gathering of the leaves commences in September and October and is continued throughout the winter whenever a thaw takes place. The yield is largest in spring before the plants come into flower. According to the season a hundred-weight of Spinach leaves will fetch from 6s. 3d. to 16s. 8d. in the market.

The varieties most suitable for field culture are:

1. EPINARD MONSTRUEUX DE VINCENNES, which has exceedingly large leaves.
2. EPINARD A FEUILLES DE LAITUE, the leaves of which are closely set, roundish oval in shape and very green.

3. EPINARD LENTA MONTER, which in spring continues in full bearing for

about three weeks after the other kinds have come into flower.

It has been observed that Spinach, belonging to the natural family of the Chenopodiaceae, does badly if sown in ground from which a crop of Beetroot (which belongs to the same family) has last been taken, and this is one of the reasons why it is recommended to sow Spinach on a Corn stubble.

Sorrel is frequently grown in the same way, but being a perennial lasts longer in the ground. At Varedes, not far from Paris, a very well-managed and prosperous branch of industry in connection with this plant is carried on by M. Clairet, in whose establishment the Sorrel leaves are boiled and made into a paste, which is sent out in boxes or barrels very ingeniously contrived so as to prevent the paste from drying

A woodland walk. Engraved for THE GARDEN from a photograph sent by Mr. S. W. Fitzherbert, Torquay.

why they should not also be grown in this way in any locality where a pickle factory can be established.

The seed is sown about the beginning of May, when the ground has become warm, in pockets, which are made in the soil in lines about 6½ feet apart. Usually some other kind of vegetable, most frequently Haricot Beans which are to be gathered green, is grown in the intervals between the lines of pockets. The crop commences to come in in July, and is produced continuously until September. The variety which is grown in the fields is the Cornichon vert de Paris, the fruit of which is spiny, very green, and continuously produced in almost inexhaustible abundance. The Gherkins are gathered when they are about the thickness of the little finger, but at every ensuing gathering there are

up and also to neutralise the corrosive action of the acid salt of the Sorrel upon the metal of which the boxes, &c., are made.

The best variety of Sorrel for field culture is the Oseille large de Belleville.

#### STRAWBERRIES.

The culture of the large-fruited kinds of Strawberries should be placed almost on the same footing as that of Asparagus, if it is to be carried out with the justice which is due to it. The experience of forty years' successful culture testifies to the economic importance of this crop in the neighbourhood of large towns. Strawberries bear carriage badly, and it is more difficult to send them to any considerable distance in good condition than any other fruit which is grown in our climate; consequently a considerable preference for excellence is given to those Strawberries which are grown not far from the markets to which the fruit can be sent in a very short time without being exposed to the detrimental effects of very hot weather or of too much shaking and jolting on the journey. In the neighbourhood of Paris, the Strawberries which are grown for the Halle market are cultivated on the edges of valleys, on well-exposed slopes of rising ground, and (favourite position of all) on declivities from which trees and shrubs have been cleared off. The quantity of water in the annual rainfall is generally quite sufficient for the plants which are grown in this way, and they never receive any artificial watering. A plantation ordinarily lasts for three years, yielding half a crop in the first year and full crops in the two succeeding seasons. Planting is done either in April or September as weather or circumstances may permit, and after the third season's crop is gathered the plantation, being no longer sufficiently profitable, is rooted up. The good qualities which a variety of Strawberry should possess to recommend it to cultivators are many in number. In the first place, I may mention earliness in bearing, which ensures a high market price at the commencement of the season; then vigour of growth, maintaining an abundant production; colour in the fruit, which renders it more saleable; and as great a capacity as possible for bearing carriage without injury, so that it may be quite fresh when it reaches the market.

The following seven varieties are favourite ones with the growers in the neighbourhood of Paris, and can be recommended as well adapted for field culture:—

1. **FRAISE MARGUERITE** is highly esteemed for the earliness and large size of its fruit, which is rather pale in colour and deficient in quality, yet sells very well until the ordinary early kinds come to market.

2. **PRINCESSE ROYALE** is an old French variety, which is still highly thought of by the growers around Paris. It is very early, very productive, and highly coloured. The central part of the fruit is so solid and tough, that it is known at the Halle market as the "Fraise a noyau," or "Strawberry with a stone."

3. **DOCTEUR MORÈRE**.—An early, large and very productive kind, of excellent quality. The fruit is palish in colour and prone to grow hollow at the centre; nevertheless it is highly deserving of recommendation.

4. **VICOMTESSE HÉRICART DE THURY**, commonly abbreviated to "Ricart," is a very early kind with a fine colour and of exquisite flavour. This is by far the best variety of Strawberry for field culture. It has only one drawback, viz., that the fruit is rather small-sized, and now-a-days in the markets a fine appearance goes before excellence of quality.

5. **JUCUNDA**.—This is the most productive, the hardiest and the most vigorous-growing variety of all. It is not a very early-fruited kind, but

bears plentifully and for a long time, and the fruit is very fine-looking and well coloured.

6. **SIR JOSEPH PAXTON**.—This variety is beginning to be more extensively grown about Paris. It bears a superb, large, conical, well-shaped fruit with a magnificent colour. It is a very late kind, but is none the worse for that.

7. **BELLE DE COURS**.—This is in every respect one of the handsomest and best kinds of Strawberries, early and very productive. The fruit is long in shape and of a handsome deep colour, shining as if varnished and excellent for both quantity and quality.

When Strawberries are grown on a large scale for market it is advisable not to confine oneself to a single variety, but to divide the ground between two or three varieties which ripen at different periods. In this way the grower is not only secured from the risk of losing too much through the occurrence of unusually unfavourable weather, which might hit one variety very hard and do very little harm to the others, but he can also distribute the work of gathering the fruit over a longer period and profit by the generally higher market prices which prevail both at the commencement and at the end of the season.

#### HARICOTS OR KIDNEY BEANS.

With regard to the special subject of which I am treating, no other vegetable presents so much difficulty as Haricot Beans, on account of the great variety of ways in which they may be grown in different localities and sometimes in the same locality—hence a correspondingly large number of distinct varieties and of different modes of culture has to be taken into account. Requiring more heat than moisture and growing rapidly, Haricot Beans are easily grown as a summer crop, succeeding any other crop which is cleared off in spring (such as early Potatoes, Spinach, or Red Clover), and at the end of September leaving the ground free for the sowing of winter Corn.

From a cultural point of view, these Beans are divided into two classes, viz., the tall kinds, which require the support of stakes, &c., and the dwarf kinds, which are of low, tufty growth and need no stakes. It is of these dwarf kinds that I shall here treat in connection with field culture, as the taller-growing kinds, which require the support of stakes, come rather within the province of market gardening properly so termed.

In the matter of table use, these Beans are divided into the edible-podded (Haricots sans parchemin or mange-tout) and the tough-podded (Haricots à écosser or à parchemin). The pods of the first-named kind can be eaten as well as the seeds, whereas the pods of the last-named kind are only eaten in the young or green state, and the seeds or Beans are eaten both when freshly shelled and also in the dried state, in which latter condition they are most largely consumed. In most districts of France the crops of ripe Beans, which are grown amongst other crops, as in vineyards and Maize fields, are almost equal in quantity to the Corn crops, and form an important article of the public food supply, since the seeds of leguminous vegetables, and especially these Beans, are the least expensive of the substances which furnish the nitrogenous elements of food.

It is very difficult to say which varieties of Haricots are the best to grow for the ripe seeds, some being preferred by cultivators for one reason, and others for a different one, while the taste of the purchaser must also be taken into consideration, as it often counts for a good deal in the very different prices realised for two articles of equal intrinsic value, but of which one is in fashion while the other is not.

Generally speaking, the white-seeded kinds are always preferable, such as the White Flageolets à feuilles gaufrées and hâtif d'Etampes, which are of first-class quality, Haricot de Soissons nain, nain Bonnemain, and Haricot riz nain, or Comtesse d'Chambord. The Haricot suisse blanc (and especially the dwarf variety, which does not run at the top) and the Haricot sabre nain d'Hollande may also be confidently grown for a crop of dried Beans, which as long as they are in good condition will always find a purchaser.

The greenish seeded varieties, Chevrier, Merveille de France, Bagnolet vert, &c., are still more valuable than the white-seeded kinds; but in order to have them well coloured and very uniform in appearance, Nature must be in some degree assisted by the labour and skill of the cultivator. As soon as growth has ceased (which is easily known by the falling of the leaves), and while the pods are still fresh, the plants should be pulled up and placed in small heaps not quite so large as those into which mown Grass is first made up in hay-making. The leaves of the plants and, if necessary, a little straw are used to cover the heaps, in order that the pods may dry gradually, and to exclude light as much as possible. In about from ten to fifteen days, if the weather is favourable, the Beans will be well dried, and may be threshed out.

Amongst the coloured Beans which are in demand for table use, I must mention the Haricot Flageolet rouge or rognon de coq, which is long and cylindrical in shape, very glistening in appearance, and always high in price, and the Haricots nains de Chartres and d'Orléans, which are smaller, shorter, and olive-shaped, and are very largely consumed by country folk. The Haricot's suisses sang de bœuf, suisse rouge or indien, and H. ture are abundantly supplied in a dried state to the Halle market at Paris. The crop can always be gathered within the space of five months from the time of sowing, and a still shorter period suffices for those kinds of which the Beans are consumed in the fresh or undried state, while those of which the green pods only are eaten are cleared off in the shortest time of all.

In the neighbourhood of Paris, where varieties of which the Beans are only consumed in the undried state are pretty extensively grown, three kinds are almost exclusively cultivated. Two of these I have already mentioned, viz., the Haricot Flageolet blanc and Soissons nain. The third is the H. Flageolet jaune, a very early, vigorous-growing and productive kind, the large, plump and very delicate flavoured seed or Bean of which is almost white at any period of its growth before it is dried. The Beans of the Flageolet rouge are also, but more rarely, consumed in the undried state.

For the supply of pods which are to be consumed in the green state (a very important part of this culture in the neighbourhood of all large towns, and of Paris in particular) the number of varieties which are in favour is almost unlimited. In one village district where the cultivators devote themselves to the supply of green pods, fifteen different varieties are grown, each of which in some particular point merits the preference which is given to it.

For furnishing the earliest green pods that are sent to market the varieties Flageolet d'Etampes, Noir de Belgique and Chocolat are equally good. The advantage of earliness, however, is accompanied with the drawback of a smaller yield than that which is produced by later bearing kinds, and it has now lost very much of its importance in consequence of the supplies which are sent from various districts

where the climate is more favourable to early growth than that of Paris. These green pods, like Asparagus, but in a less degree, bear carriage well and are sent to Paris from Bordeaux, Provence, and even from the south of Spain.

For the general or main supply of the season the preference is given to free-bearing kinds the pods of which are long, straight and cylindrical rather than too much flattened in shape, and of a fine green colour, without any dark streaks or markings. The dwarf kinds which are grown for the production of green pods should not be too short stemmed, otherwise the long pods, coming into contact with the ground, are liable to have their extremities dirtied and frequently rotted by the damp soil.

The following are the principal main-season dwarf kinds: Haricot Bagnolet or Suisse gris, one of the kinds most generally grown about Paris. It is not a very early variety, but is extremely productive, hardy, long-lasting and continuous bearing. There is a sub-variety of it which has crimped leaves. H. Solitaire is another form of H. Bagnolet, with a more branching or bushy habit of growth and smaller-sized seeds or Beans. This, it is said, received its name from the circumstance that only one Bean of it is needed, in planting, to form a rather thick or bushy growth. Be that as it may, the practice now is to plant three or four beans of it together in each pocket, in the same way as the other kinds are planted.

The variety named Gloire de Dijon is ten days earlier than the Bagnolet and bears broader pods and not so abundantly. The two kinds might be grown together, so as to secure from the combination both an earlier crop and also a plentiful and long-continued one. The Haricot Russe, which is somewhat taller and not so branching in growth, resembles the Bagnolet in the length of its pods. Its seeds or Beans are of a dull grey colour and not glistening like the beans of the other varieties. The H. Flageolet noir is still grown to some extent about Paris. It has a rather delicate constitution, but its long pods are remarkably handsome in appearance. The variety Shah de Perse is coming more and more into favour for the production of green pods, as it furnishes longer, straighter, and finer looking pods than any other dwarf variety. The plant is of very vigorous growth and bears broad leaves. This variety does best in soils which are constantly more or less moist up to a certain degree.

The culture of the edible-podded or mange-tout varieties may be in some measure compared to that of kinds whose pods are gathered while green. In both cases the pods are eaten together with their contents, but the pods of the mange-tout kinds are usually allowed to become more advanced in growth, so that the Beans which they contain are more or less fully formed when the pods are gathered for table use.

The best known and most highly esteemed of all the edible-podded kinds in the neighbourhood of Paris is the long-podded Haricot Beurré noir nain. This is clearly distinguishable from the old-fashioned H. Beurré noir nain or noir nain d'Alger by the wider intervals between the Beans in the pod. The Beans also are longer and narrower at the ends. The pod, instead of being short and thick, is almost as long as the pod of a Flageolet. The plant is vigorous-growing, hardy and very productive. The Haricot nain mange-tout extra-hâtif and the H. Beurré blanc nam are also to be recommended for the whiteness of their Beans, and the first-named of these varieties for its special earliness.

Amongst the edible podded kinds with green or coloured pods I may also mention Haricot nain unique, an exceedingly productive and hardy kind, bearing numerous thick pods, and the singular H. nain à cosses violettes, an early and free-bearing variety, the pods of which when boiled lose their natural deep violet colour and become as green as those of any other kind.

The cultivation of a crop of Haricots or Kidney Beans does not occupy the ground for too long a time, and it mostly leaves the soil clean and fertile for some other crop to follow. This is one of its recommendations. When the plants are grown for the sake of the ripe Beans only, the crop does not demand anything like the amount of hand labour that is required when they are grown for the green pods.

(To be continued.)

## THE PEA AND BEAN WEEVIL.

(SITONES LINEATUS.)

THE Board of Agriculture have received complaints of damage having been done to Peas by a weevil, which feeds upon several leguminous plants. This insect is recognised as the Pea and Bean weevil, to which attention was drawn by the Board in 1892. Peas and Beans are very subject to attacks by this insect, but the injury is frequently attributed to slugs, because the weevil is not by any means easily seen. It is of a dull colour, and falls to the ground on the least alarm. The weevil itself eats the leaves and young shoots of the Pea and Bean plants, and its larvæ devour their roots. It is often most troublesome in market gardens and allotment grounds, and in some years an extensive reduction in the crops of Peas and Beans has resulted from its attacks. It has been known also to attack Sweet Peas in gardens. It sometimes seriously injures red Clover in its early stages, and its small white maggots, or larvæ, also spoil "second cuts" of Clover by eating the roots of the plants and stopping their growth. Trifolium, too, suffers considerably, particularly in its early stages, from the attacks of this weevil, although the injury is generally attributed to slugs and other insects.

### DESCRIPTION AND LIFE HISTORY.

The Pea and Bean weevil is a quarter of an inch long. Its ground colour is dark, but the body is covered with greyish scales, which in some specimens are of a slightly greenish shade. There are three lines of this grey, or grey-green, hue on the thorax, and many lines on the wing cases. The antennæ are of a red colour, very slender, with club terminations. The legs are ferruginous. As Canon Fowler says, "the tibiae of the male are curved and armed with a small hook." It is not known where the eggs are placed. Egg-laying begins in the early spring. The larvæ, or maggots, which are white, legless, nearly a quarter of an inch long, and somewhat curved, live in the roots of Clover, Peas, Beans, and other leguminous plants, and there change to pupæ.

It is certain that some of the weevils pass the winter in weevil form. Probably, in other cases hibernation takes place in the pupal state, though this is not definitely known. Nordlinger observes that many weevils come from the pupæ at the end of August, and without doubt hibernate in weevil shape. From observation, it is plain that these insects hibernate in the perfect, as well as in the pupal state. Larvæ have also been found at all seasons of the year among the roots of Clover. A favourite resort of the hibernating weevils is in the straws of stubble. They are also carried in quantities with Peas and Beans into ricks and barns. These weevils feed by night as well as by day.

### METHODS OF PREVENTION AND REMEDIES.

Lime and soot, either alone or mixed, may be advantageously distributed over infested plants

while the dew is upon them, or after rain. Finely-powdered guano also may be used in this way. Applications of weak solutions of paraffin, with a little soft soap, would make infested plants distasteful to these insects. Fine powdery materials can be easily applied and well distributed with knap-sack machines.

When Peas and Beans are attacked, it would be desirable to press the earth tightly and firmly close round the plants, in order to prevent the beetles from coming up from the earth. This might be done by men and boys walking with a foot on either side of each row of plants. Summer-fallowing of land after an attack would be very desirable. Wheat after Clover ley is often infested by swarms of weevils. In this case it would be dangerous to sow Trifolium at all. If it is sown the land should be "broad-shared," or cultivated and ploughed. The stubble should be burnt. The burning of stubble, weeds, roots, and rubbish is comparatively seldom adopted in these days. It is believed that the infrequency of this practice is one cause of the more frequent and more destructive visitations of insects injurious to crops. Infested Clover leys should be deeply ploughed, with a "skim" coulter on the plough, and thoroughly well pressed. Roots on the top should be removed and burnt, not carted to the outsides and left in lumps.

### A MAY MORNING.

THE great Tree Peony's creamy flowers are drenched with last night's heavy dew, and in one of them an iridescent-winged Rose beetle brushes glistening drops from the satin petals. The bland air, whose every breath is a benediction, gently sways the heavy heads of the yellow Tulips that, last of their race, glow beneath a northern wall. The Forget-me-not border under the Lilac tree is a hazy mist of blue. Against a background of sombre Yew the first of the large scarlet Poppies blazes. The land is a land of promise—promise of profuse blossoming, of bountiful verdure. The bank of Azaleas and Rhododendrons is hourly enlarging its coloured mantle—daily adding tint to tint. The white Lilac is even now in full flower, just beating her coloured sister in the race, in which Laburnum and pink Thorn, Syringa, and Guedler Rose will not be far behind.

At the far end of the lawn, as six sonorous notes ring out from the deep-toned bell in the neighbouring church tower, a chaffinch, startled from her nest in the Ivy clad summer-house, chirps querulously, less placid than the green linnet that has built between the layers of the Deodar's boughs, which sits on in patient expectancy, heedless alike of the belfry's call to prayer or praise—of summons to the altar or the grave.

In rapid flight, now high, now low, the swallows pass and re-pass, while far above, in an azure sky, wheel the black arcs of the swift's wings. From the topmost sprig of the Wellingtonia a thrush is singing, and distant echoes reiterate the euckoo's call.

The day is an interlude—an interlude of peace. The hour is an hour of which the keynote is quietude. Restful to the eye is the old house embowered in blossom and leaf, the flowers of the Wistaria mingling with the glossy foliage of the Magnolia—Rêve d'Or Roses with Clematis and Jasmine. Restful the view to the southward—the sight of field succeeding field, hill swelling into hill, blue distances melting into bluer atmosphere, but most restful of all, in the hush of the spring morning, is the orchard. There let us wend our way, strolling past the Cedars, with their memories of other climes—past the arbour, which in another week the Laburnum will have shrouded in a golden veil—past the great Chestnut, whose giant limbs are lost in a wealth of verdant fans, and whose blossoms are already whitening towards perfection—to where, marked only by the light railings and sudden, foot-high Grass on the further side, lawn merges into orchard. An orchard less profitable than picturesque, with gracious vistas gently sloping westward—vistas canopied with the pink and

white of Apple blossom, carpeted with Buttercups and Lady's-smocks that almost hide the emerald of the lush-green Grass now growing so strongly. Happy aisles of Lichen-covered trunks, in whose recesses the green woodpecker has made her nest. Surely there are few more beautiful sights than such an orchard in the early hours of a May morning. S. W. F.

## NOTES OF THE WEEK.

**Dianthus callizonus.**—This rare and beautiful alpine Pink is well grown at Kew, where we noted several specimens in the house devoted to alpine gems, all of them flowering freely. It is quite distinct from other species, the flowers large, of a soft rose colour, with a darker rosy zone in the centre covered with tiny white spots.

**Cattleya Mendeli.**—The Hon. Miss Winn sends you a *C. Mendeli*. Please say if this is what is called a white form, and what you think of it.—J. EASTER, *Nostall Priory*.

\* \* A very beautiful form, but, unfortunately for you, not the white *C. Mendeli*. The flower you send is very richly coloured, a well marked and delightful variety.—ED.

**Viburnum pyriformum.**—A large specimen of this old, but little-known North American species is flowering freely in the grounds at Syon House. It is 12 feet or more in height, with a wide spread of branches. The leaves, as the name implies, are like those of a *Pyrus*, and the flower-clusters resemble those of the Wayfaring Tree, but are whiter.

**Hydrangea Thomas Hogg.**—There is a remarkably fine specimen of this white-flowered form in the exhibition house of the Botanic Gardens, Edgbaston, Birmingham, which has produced about 100 trusses, and a noteworthy feature is that the corymbs are all of such good average size. It thus makes a noble conservatory plant.—R. D.

**Abutilon vitifolium.**—Mr. Hartland sends us from Cork beautiful flowers of this in clusters of four or five, the blooms very large and of a lovely pale lilac shade. It seems a little different from other forms we have seen. He says that the birds build their nests in the trunk of the tree, but he does not tell us whether a wall is needed to flower it in such perfection.

**Viburnum plicatum** is not a shrub one would recommend for training on walls, but a plant on the wall in the R.H.S. Gardens, Chiswick, is a perfect picture of profuse bloom. It is covered so thickly with its flower-clusters from bottom to top, that scarcely a green leaf is visible. Bushy plants in the rock garden are only thinly flowered, so that it would appear as if the wall treatment was more favourable.

**Forget-me-nots.**—I enclose you three varieties of *Myosotis* which, amongst others, I have raised from seed. No. 1 is a very strong growing var. and rather tall; No. 2 grows very compact and dwarf. All the varieties are beautifully scented. I should be very pleased to have your opinion of them.—ARTHUR RHODES.

\* \* Lovely forms of the wood Forget-me-not, worthy of further trial.—ED.

**Rosa nutkana** is a vigorous and handsome single Rose, conspicuous even among many kinds in flower at Kew. The bush is quite 8 feet high, and the shoots have few spines. The flowers are large, numerous, and of a soft pink colour. There seems to be some uncertainty, however, as to the true *Nootka* Rose which we have seen described in the *Garden and Forest* as one of the finest wild Roses of Western America, the flowers white, both flowers and fruit larger than those of any other American species.

**Hieracium villosum.**—The *Hieracium* family and its kindred are a host chiefly of weedy character, but an exception must be made in favour of one or two kinds that deserve some attention, especially the subject of this note, now flowering

finely at Kew. The Shaggy Hawkweed is an appropriate name for it, as the leaves and flower-stems as well are covered with white shaggy hairs. The flower is large, of a rich yellow colour, borne on a stem about 1 foot high. A coloured plate was given of this Hawkweed in THE GARDEN of December 29, 1894.

**Hardy flowers in masses.**—Hardy flowers in a cut state arranged in a mass of one kind give a much more decided effect than a few spikes or trusses of each. At no time have I seen the effect of masses better than in the exhibit of Mr. Ladhams at the Southampton show. The flowers shown were the following: *Henchera sanguinea*, *Pyrethrum Mont Blanc*, *Sherlock*, single crimson, and *Hamlet*, single pink, *Aquilegia chrysantha*, *Hemerocallis Middendorffiana*, *Mertensia virginica*, *Iris Mme. Chereau*, *Erigeron aurantiacum*, *Campanula glomerata dahurica*, *Achillea mongolica* and grand spikes of *Dictamnus Fraxinella*.—E. M.

**Odontadenia speciosa.**—This bold and striking scandent shrub, probably best known under the name of *Dipladenia Harrisi*, is now in fine bloom in one of the stove houses at the Birmingham Botanic Gardens at Edgbaston. This, which appears to be the only species in cultivation, is planted out at the end of one of the houses, the shoots being trained along the rafters; the flowers, produced in large cymes, are bright yellow in colour, shaded with orange, large, stout, of fine form and delicately scented. It was introduced from Trinidad in 1854. It is so interesting and handsome a plant, that one wonders it is not more frequently met with.—R. D.

**Vaccoueria hexandra.**—It would be difficult to find a more graceful hardy plant than this, which has all the elegance and beauty of *Maidenhair Fern*, and is a gem for the rock garden to associate with some bright flowering plant. A mass of it is luxuriant in the rock garden at Kew, and it is also flowering prettily as well, the flowers white, on slender branched spikes, much like those of an *Epimedium*. For its leaf beauty, however, it is most noteworthy, and it is easy to grow in free, moist soil with full exposure, planted at the base of a large rock with a cool, northern aspect. It runs freely underground and may be readily increased by division.

**Poppy Prince of Orange.**—This is a very fine variety of the Oriental Poppy, with flowers of a lighter orange-scarlet shade than those of the type. A fine group of it is in flower at Syon House, and the plants being seedlings show some slight variations, some of them having the characteristic black spot at the base of the petals, whilst in others it is entirely absent. These giant Poppies have a fine effect when boldly grouped, especially in association with shrubs. Mr. Wythes also finds them useful cut flowers for large vases, and if cut just as the buds are bursting, the flowers open in the house and last longer than when they expand upon the plant.

**Arundo conspicua.**—In answer to Mr. E. Burrell (page 369) I am glad to be able to say that, in my garden in South Devon, *Arundo conspicua* has been uninjured by the late winter, although left totally unprotected. *Berberis Darwini*, close by, has been badly injured, quite three parts having to be cut away in the spring. *Bambusa aurea* and *B. vindi-glaucescens*, beyond looking a little brown at present, have passed through the ordeal scatheless, but *Fatsia japonica* has lost most of its upper leaves, which gives it an untidy look, and its decorative appearance will not be regained until the young shoots, now breaking strongly, have fully developed their foliage. I find that *Zauschneria californica* is dead, but there are no losses among the *Montbretias* or plants of *Gypsophila paniculata*.—S. W. F.

**Crinum crassifolium.**—In the Cambridge Botanic Garden this superb species, for which we are indebted to the liberality of M. Van Tubergen, is now finely in flower. It is growing at the foot of a south wall where it has had no protection during the past winter, and is a little earlier in bloom than *C. capense*. The flowers are white

within, suffused with pink on the outside, and strike one as forming a very compact umbel. Seven out of nine are open and in good condition at the same time. The leaves of this plant are each about 2 feet 6 inches long and 3 inches broad, deep green, not glaucous, and darker than those of *C. Moorci*. The peduncle is erect, stout and about 20 inches long. The flowers, shorter than those of *C. capense*, are well formed, the tube green, about 3 inches in length, segments about as long, oblong in shape and sharp-pointed. Mr. Baker in his "Handbook of the Amaryllidaceae" places this under *C. variabile*, but it is not said whether the plants are identical. Both names were applied by Herbert. At the time of writing Mr. Baker believed that this plant was no longer in cultivation. Fortunately we have it now. It without doubt is unsurpassed in beauty among the kinds which can be grown out-of-doors, and, moreover, it possesses a charming perfume. It is a native of Cape Colony.—R. I. LYNCH.

**Iris-s.**—I send herewith a small gathering of *Beardless Irises* (*I. apogon*). That marked No. 1 is undoubtedly *I. Douglasiana*. It reached me from a sure source, and, moreover, it appears to correspond exactly to Mr. Baker's description of that species. I have, however, here another very remarkable and distinct *Iris*, as to the botanical identity of which I should like to have had your opinion, but, unluckily, the dry weather has withered the last bloom beyond recognition. I purchased this also as *I. Douglasiana*, and it is identical with an *Iris* I had here some years ago from a separate source under the same name. The growth and habit of the latter plant is entirely different from No. 1, being much dwarfier and less vigorous. The flower, too, is totally distinct, the pale pink or lilac colour being almost, if not entirely absent, while the standards are horizontal and level with the falls, giving the flower a star-like appearance. It may possibly be *I. Bechebeyana*, or the *Santa Cruz* variety of *I. Douglasiana*, but it is certainly strangely like the *Iris* described as *I. bracteata* by Herr Max Leichtlin in THE GARDEN of the week before last (p. 354), only I have never knowingly succeeded in making *I. bracteata* grow here, though I have bought it two or three times. No. 2 is one of the most beautiful of all *Irises*, *I. tridentata*. No. 3 (sold to me as *I. setosa*) is no doubt *I. versicolor*, and No. 4 is its var., *I. v. virginica*, usually sold as *I. virginica*. No. 5 is a poor *Iris*—*I. ensata*. Nos. 6, 7, and 8 I grow as *I. humilis*, *I. graminea*, and *I. prismatica* respectively. Perhaps you may detect differences. I cannot do so myself. No. 9 is the var. *orientalis* of *I. sibirica*, usually sold as *I. orientalis*. No. 10 I had as *I. coriacea*. No. 11 was also sold to me as *I. prismatica*. I see little difference in any of these three latter, except that the first, No. 9, is the finest and most vigorous plant. No. 12 is the white var. of *I. sibirica*. *I. longipetala* and *I. missouriensis* (one of the most lovely of all *Irises*) are over. *I. hexagona* and *I. Grant Duffi* have not bloomed. There is no *Iris* in my garden at this minute more beautiful than *I. pseudacorus* and its variegated var., which has yellow flowers with rather darker markings. *I. aurea*, *I. Monnierii*, *I. orientalis* (or *ochroleuca*), and the *Kampferi* vars. are to come. Many of the *germanica* sorts are flowering badly this year.—J. C. L.

## EREMURUS ROBUSTUS AND UEMANTHUS KALBREYERI.

We send you flower-spikes of the above two plants. *Eremurus robustus* is by no means new nor of recent introduction. To my knowledge it has been cultivated for the last 15 years, but for some reason or another it has till now remained a plant of little popularity. It is a noble plant and ought to be one of the most prominent hardy perennials. With a little protection of some litter during the winter it proves perfectly hardy, and has withstood the extreme and long-lasting cold of last winter without the least injury and never before produced a spike of flowers of such

fine dimensions. The culture of this plant is very easy, as proved by the fact that a good strong plant once planted in the border will flower for several years in succession, after which it will take a rest for a season or two, producing a fine head of foliage only. It requires a rich soil, and when planting the hole ought to be sufficiently large to allow of at least 1 foot of rich stable manure to be placed at the bottom, taking care though in planting not to place the roots direct upon the manure, but let that first be covered with a layer of soil. After once planted, this plant ought to be left undisturbed for years, when it will bloom better year after year. As the big fleshy roots are yearly seeking fresh nutriment it will be found very beneficial to give every spring a good top dressing, and whilst growing, a good watering two or three times a week will help the plants on considerably. Almost any good rich soil will do to grow them in, but avoid peat or leaf-mould, which is rather too porous. We flower *E. robustus* every year, but we have never seen here nor anywhere else a spike of such unusual dimensions. The whole length of the spike, from the base to the tip of the inflorescence, measures 7 feet 8 inches, of which the flowering portion occupies at the time of cutting the spike some 3 feet 9 inches, with about 420 flowers and buds on the spike.

*Thaunanthus Kalbreyeri*, introduced into commerce some fourteen years ago, is one of the finest species known, producing umbels as much as 9 inches across, consisting of some 50 to 100 pretty, graceful spider-like blooms of a rich scarlet. The foliage is of a handsome lively green, and even out of bloom this plant is very ornamental for the greater part of the summer. Bulbs the size of a walnut will readily flower. It can easily be propagated by division after having bloomed, potting it in a good sandy loam with a slight addition of leaf-mould or peat, provided with a good and free drainage to avoid any stagnation of water, of which this plant requires a plentiful supply whilst growing. Towards the autumn when the foliage begins to turn yellow the bulbs must be allowed gradually to get into a dry state, when they will winter without any danger in any temperate greenhouse provided they are kept free from blackbeetles, mice, or other destructive pests. When about February they begin to show signs of vegetation, they will require a little water, which after being repotted must be gradually increased as the growth proceeds, and for the rest treat the same as other Amaryllids.—*LOUIS VAN HOUTTE, Ghent*

\* \* A noble and robust spike of *Eremurus*. We have had them as tall in England, but we think not so robust.—*Ed.*

**The weather in West Herts.**—During May there occurred only six unseasonably cold days, but a good many moderately cold nights. On as many as eleven days the highest temperature in shade exceeded 70°, and on three of these 75°, the maximum reading for a seasonable May being about 60°. On the hottest day of all the temperature rose to 83°, which is the highest reading recorded here in May during the ten years over which my observations extend. In London 86° was registered by Mr. G. J. Symons, F.R.S., who says, "This has been the hottest May day for twenty-seven years, and the hottest but one for thirty-seven years." At no time did the exposed thermometer show more than 4° of frost. During the past month the temperature of the soil at 2 feet deep rose from 51° to 60°, and at 1 foot deep from 53° to 65°. Taking the month as a whole the ground was warmer than in any of the nine previous Mays, with the exception of that of 1893, when the readings were considerably higher. Rain fell on only five days and to the aggregate depth of but half an inch, which is more than 15 inches below the mean for the month. Although the Berkhamsted rainfall tables reach back to 1856, there is no previous instance of a May quite as dry as this. In May, 1884, the fall of rain was, however, nearly as light. No rain at all has come through the light soil percolation

gauge since the middle of May, but the drainage through the heavier soil did not entirely cease until twelve days later. On May 30 the atmosphere was so dry at 3 o'clock in the afternoon, that the difference between the readings of the dry and wet bulb thermometers amounted to as much as 21°. May was a remarkably sunny month. On no fewer than fifteen days the sun shone brightly for over ten hours, and on four of these for over thirteen hours. In fact, this was not only the sunniest May of the past ten years, but during that period there has been only one other month when the average daily duration has exceeded it, and that was in July of the Jubilee year. A large bush of the wild Dog Rose growing in my garden came into blossom on May 30, or on the same day as last year, but six days earlier than its average date of flowering in the previous nine years. I cut my first Tea Rose (*Souvenir d'un Ami*) from the open ground on the 4th inst., which is ten days in advance of the nine years mean.—*E. M., Berkhamsted.*

## PUBLIC GARDENS.

**New open space for Woolwich.**—Her Royal Highness Princess Louise, Duchess of Fife, who was accompanied by the Duke of Fife, lately opened St. Mary's Churchyard, Woolwich, as a recreation ground for the public. The churchyard is about 4 acres in extent, and a donation of £1200 to enable it to be laid out as a place of public resort was given by Mr. J. Passmore Edwards. The Metropolitan Public Gardens Association have tastefully carried out the work, and the new open space will undoubtedly be a great boon to a populous locality. The Earl of Meath, in explaining the objects of the Association and its connection with the laying out of the ground, stated that the present was the eighty-first space that it had been instrumental in opening to the public, the extent of ground laid out being about 120 acres, representing a cost of some £40,000. The Association had likewise planted thousands of trees throughout the metropolis, and it had work in hand on six grounds at the present moment.

**Opening of Bethnal Green Gardens.**—It is doubtful if any open space in London was bought for the public 200 years ago, except that at Bethnal Green, which was formally opened yesterday by Mr. J. S. Fletcher, J.P., chairman of the Parks Committee of the London County Council. Two hundred and five years ago, when Bethnal Green woods was a favourite hunting resort of the citizens of London, Lady Wentworth (the then owner of the manor of Stepney) was anxious to let certain portions of the land for building, but several of the "nobility and gentry" who then dwelt in the "hamlet of Bethnoll Green" were equally anxious to prevent any incursion of the forerunner of the jerry-builder, and they bought for £200 some 15 acres of land and set it apart for public uses. On a portion of the land so acquired Bethnal Green Museum and gardens are now situated, and the remaining portion was purchased from the trustees by the London County Council for £8000, or some forty times its value 200 years ago. This portion, which comprises 6½ acres, has been tastefully laid out as a public garden, with a gymnasium attached for children.

**The Royal Gardeners' Orphan Fund.**—At a meeting of the committee held on the 31st ult. at the Horticultural Club, Mr. William Marshall presiding, the secretary announced that the late Mr. George Taber, senior partner in the firm of Messrs. Cooper, Taber and Co., seed merchants, Southwark Street, had bequeathed as a legacy to the firm four twenty-five pound shares in the company. The following special donations were announced: Mr. John Wills, 16, Onslow Crescent, S.W., the fifth annual birthday gift of £10 10s., with an intimation that for the next five years the sum would be increased to twenty guineas; from

Messrs. J. Waterer and Co., Bagshot Nurseries, £10; proceeds of a concert at the Shackleton Institute, near Godalming, per Mr. G. P. Baskett, £8; and from Mr. W. Evans, Wharfedale, Leeds, 5s.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday next, June 11, at 3 p.m. A lecture will be given by Mr. Frank Cant on "Rose Culture under Glass." The president of the society will also present the Veitchian Memorial medals to Mr. James Bateman, Mr. F. W. Moore and M. Victor Lemoine, of Nancy.—*J. W.*

**The Birmingham Botanic and Horticultural Society.**—A very interesting ceremony took place at the Botanic Gardens, Edgbaston, on the 29th ult., it being the occasion of opening the new alpine garden, and which is to be known as the High Nettlefold Alpine Garden, it being dedicated to the memory of this gentleman. The opening ceremony was performed by Mr. Geo. H. Kenrick, chairman of the Improvements sub-committee, who are in charge of a scheme which commenced with a considerable extension of the exhibition hall last year, and is intended to include among other things the lighting of the houses and terrace by means of electricity, and the institution of a system of popular botanical and horticultural lectures. As it was the first day of the Pansy and Viola show there was a considerable attendance of subscribers and others. In constructing the garden 250 tons of millstone grit from Yorkshire were used, in masses varying up to five tons, and it covers an area of nearly half an acre. The water supply is natural, due to two springs which were tapped in the progress of the work; attached is a bog garden. Owing to the exceptionally dry season, the planting is by no means complete, many subjects being left over until the autumn. The work was commenced in October last.

## OBITUARY.

**Mr. Robert Henderson.**—This skilful gardener, we are sorry to hear, has passed away at the age of seventy-one years. Of recent years he has lived in retirement, but visitors to the historic grounds of Fulham Palace will remember him with kindly feelings. He was gardener to the late Bishop Jackson, having previously served under him when Bishop of Lincoln—altogether a period of thirty-four years. Mr. Henderson loved well the many fine and interesting trees in the Fulham Palace grounds, and we have recollections of pleasant visits in his company to this suburban retreat, which showed in many ways how thoroughly he understood his work. He was buried at Fulham on Wednesday last in the presence of a gathering of old friends.

**Names of plants.**—*R. B.*—The Oak Currant: A gall produced by *Cynips quercus pedunculæ*.—*John Falconer.*—Remarkably fine forms, but we do not think they are worth varietal names.—*G. B. B.*—1, *Spiraea Reevesiana*; 2, *Hemerocallis flava*; 3, *Spiraea Banalda*; 4, next week.—*J. C. L.*—*Pavonia mollis.*—*Dunum.*—*Stanhopea eburnea.*—*J. Cranston.*—1, *Spergularia arvensis*; 2, *Mercurialis perennis.*—*S. N. T.*—1, *Silene alpestris*; 2, *Caragana triflorus*; 3, *Saxifraga hirculus*; 4, *Agrostemma coronaria*; 5, *Polystichum aculeatum*; 6, *Collomia coccinea.*—*Blisters.*—Looks like the leaf of one of the *Vriesias*. Please send a flower. Vine leaves query next week.—*W. J. P.*—1, *Clematis*, cannot undertake to name varieties, there are so many; 2, *Cassandra calyculata*; 3, *Cerasus serotina*; 4, send in flower; 5, *Herniaria glabra*; 6, *Sedum Sieboldi* type and variegated variety.—*E. P. Anderson.*—*Rhododendron catawbiense* var., or a hybrid with that species largely predominating.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. 1c. 4s. 8vo, linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

No. 1230. SATURDAY, June 15, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHARD AND FRUIT GARDEN.

## THE BEST EARLY PEACH.

WHICH is the best early Peach? is a constantly recurring question. Hitherto I have recommended either Early Alexander or Waterloo, being of opinion that they are practically identical. I did not arrive at this conclusion without giving a fair trial to what I had supplied to me from different sources, but even then am by no means certain that Alexander had not been sent to me in the place of Waterloo, the latter being the later of the two introduced from America. When Early Alexander was becoming popular I ordered two trees of it from a well-known firm of nurserymen, planting one in an early house and the other in a successional compartment. Both trees grew satisfactorily, but imagine my disgust when that in the early house proved to be Alexandra Noblesse, a comparatively late variety, while that in the successional compartment turned out to be Crimson Galande. Whether or not the two American varieties are distinct, they are superior to anything in the way of early Peaches raised in this country. Early Beatrice is nearly or quite as early in ripening, but as far as appearance goes is poor compared with Early Alexander or Waterloo, and I do not admit its superiority in point of flavour. From a market grower's point of view neither Early Beatrice, Early Leopold, nor Early Alfred are worth house room, and as a private gardener I would only recommend them for pot culture where variety hath its charms. Early Rivers might have been a formidable rival to Early Alexander if only three parts or more of the fruit could be prevented from splitting from the base upwards. I have repeatedly tried fertilising the flowers of this variety with the pollen of Bellegarde, Royal George and other free-setters, but cannot say much was gained by this experiment, the stones splitting very much as in former years. What few fruits were sound attained to a great size and perfection, those well exposed to the light being very prettily coloured.

The one great fault of the American varieties, and to which attention has been repeatedly drawn in these pages, is the proneness of the trees to casting their flower buds prematurely. It happens under such very different conditions and under treatment that answered remarkably well in the case of other early and second early varieties, that it cannot well be attributed to faulty culture. When, therefore, a variety is forthcoming possessing the best qualities of Early Alexander and Waterloo without their one great defect, this ought to be welcomed and generally grown. In Amsden June we apparently have this improved variety, which, although sent us from America soon after the others above-named, has not made much headway. Mr. G. Wythes, of Syon Gardens, has brought the great value of this variety into prominence, and, thanks to his efforts, a first-class certificate was gained for it from the fruit committee of the Royal Horticultural Society in the spring of 1893. The tree from which the fruit was gathered was planted in the Syon Gardens in November, 1890, and now occupies a roof area of about 20 feet square. In May, 1892, seven dozen fine

fruits were gathered from it, and in April, 1893, nine dozen fruits were had, gathering commencing as early as April 12. This season there were fifteen dozen left on the tree and the gathering commenced on April 20. Seeing that all the fruits were moderately large and highly coloured, ripening, too, when such fine Peaches were worth probably £3 per dozen in the market, it must be conceded that this is the market grower's Peach. I made particular inquiries as to the bud-dropping, and found that Mr. Wythes has not been troubled with this failing in his tree either during this or any previous season. The quality is considered decidedly good, but of this I am unable to speak from experience, although I heartily wish that my half dozen trees of Early Alexander could be transformed into Amsden June before next season.

Descriptions of, and opinions upon, the merits of Amsden June vary considerably, and this, again, points to want of care on the part of nurserymen. Some of them may think they are supplying the genuine article, but may have been misled themselves. In the "Fruit Manual" Amsden—presumably meant for Amsden June—is described very favourably, but the fruit is said to part freely from its stone. Other authorities either describe it as shy-bearing or else ignore it altogether, while some private growers of my acquaintance speak of a perceptible bitterness in the taste. What Mr. Wythes is growing is neither a freestone nor a clingstone, but something between the two. Not till the fruits are fully ripe does it separate freely from the stone, while there is no bitterness of flavour to complain of any more than there is in the other early Peaches. Will some impartial American authority on Peaches help us in clearing up the distinctness, or otherwise, of the three American varieties I have named, their relative values also being given? From Mr. Wythes's standpoint very much valuable house and wall space in this country is wasted on the shy-bearing Early Alexander and Waterloo that would be far more profitably devoted to the sure-bearing Amsden June—similar to what he is cultivating.

W. IGGULDEN.

**Peach Early York.**—This is one of the very best of forcing Peaches, and worthy of a place in all early houses. It is not quite so large as some other varieties, but its free setting and cropping qualities, combined with excellence of flavour, atone for this. It is grown in several gardens in this neighbourhood, and always gives the greatest satisfaction. The short time it takes from commencing the second swelling until the fruit is ripe is astonishing, being very little behind the American varieties in this respect. Should any reader be thinking of adding another sort to his early or second early house, let him give Early York a trial, and he will not regret it. I have seldom known a tree of this Peach to give any trouble by bud-dropping when started.—J. C.

**Grafts on Pear walls.**—In hot situations on walls Pear grafts often do indifferently, many failing altogether. This is not to be wondered at, as the scions, as yet un-united and having only the small quantity of stored-up sap to support them, become literally baked up. This may in a great measure be prevented by daily syringings, which keep the clay from cracking badly and admitting the air. I always cover the clay with Moss, tying the same securely by means of matting or soft twine, thus further aiding in preserving the clay in a moist condition.—C.

**Apple Earl.**—This is one of the most useful Apples grown in this district, young trees after once commencing to bear doing so almost every year. The fruit, though larger, is not unlike

Normanton Wonder in appearance, and although fit for use in October will keep sound and sweet till March. It cooks beautifully, and is a delicious sauce Apple. This Apple is known in this neighbourhood under another and purely local name, but I have found that the correct name is Earl. Market growers intending planting for profit would do well to give this Apple a trial, as if as free and good generally speaking as it is hereabouts, it certainly would be worthy of extensive culture. Outwardly it is of a beautiful golden colour, the flesh being white in the extreme.—J. C.

**Strawberries for forcing.**—"W." (page 365) questions if any variety of Strawberry has given a better return than Noble. I think if he were to try Royal Sovereign and Noble under precisely similar conditions he would find the former the more satisfactory both in weight of crop, earliness of ripening and flavour. Royal Sovereign has proved this year to have an even more robust habit than Noble, which surpasses all other varieties in this respect.—S. W. F.

## APPLES FOR CIDER OR MARKET.

IN some parts of the west of England there is every prospect of a heavy crop of cider Apples, which is not altogether a blessing, for when this class of fruit is very plentiful, farmers and others, after making all the cider they consider requisite for their own requirements, desire to sell the remainder of their Apples either to cider manufacturers or to other farmers who have been less fortunate with their crops, but owing to abundant supplies the price is so low that it scarcely pays for the labour and expense of picking, measuring, and carting. Some years ago the crop of cider Apples was so great that touts actually rotted on the ground, or were eaten by cattle and pigs. Unfortunately, many of the orchards are planted with varieties of Apples that are utterly useless for any purposes other than for cider, as they will neither bake, boil, nor stew; consequently if the demand for this fruit is indifferent or bad, they are of no value except for a purpose which I think they are useful—in making a certain dye; the demand, however, is only very limited. There can be no doubt that it would be to the interest of planters of cider Apple trees if they selected those varieties that are valuable for their cider-making qualities, and also for market in seasons when it will pay best to dispose of them for cooking purposes. There are many sorts combining both those desirable elements, and when the best samples will realise from 7s. to 12s. per cwt. there is no question as to the wisdom of consigning them to market. Not only so, but all the small or damaged fruit can be utilised for cider, thus avoiding any waste and making the most of the crop possible. In some of our standard orchards we have a fair lot of the variety named Kingston Black, which is considered in the west one of the best cider Apples known, the liquor being of a superior flavour; therefore the demand for this sort is usually very good, but for years I have sent all the largest fruit to market, as it realises a good price through its very deep red colour, fair size, and handsome appearance added to its excellence for cooking. Cherry Pearmain is another cider sort of repute. It cooks well, is fair for dessert, a nice size and the trees when on good soil are enormous bearers; in fact there are many varieties of Apples far from being so profitable as this one. Herefordshire Beautin is frequently employed for cider making, though usually catalogued as a culinary variety, and should be more extensively planted by those who are anxious to have cider and market fruit from the same trees. The fruit is rather flat, highly coloured and produced in great abundance. Another advantage is its excellent keeping qualities. I have had it perfectly sound and plump at the end of May. Cowarne Red and New Redstreak are both very handsome cider Apples, also useful for market, as they cook well and combine a pleasing appearance with heavy cropping

powers. No doubt there are other varieties equally as well adapted for cider or market, but the sorts named have proved the most suitable with me, and I would suggest to any growers owning all or any of the varieties mentioned the application of a thorough soaking of liquid manure in a diluted form several times this summer if possible. Why I recommend this application now is that the effect will be practically immediate in its action, and will cause the fruit to swell to a large size, whereas chemical manures would be much slower in operating unless washed down to the roots by rain or watering. While not recommending the planting of cider Apples for market work alone, I can speak from experience how well they repay the grower for cultural attention and a liberal diet provided for their roots, as the fruit attains a size that entirely alters its appearance, so much so, that old men who had known the varieties all their lives, have been unable to recognise them.

W. G. C.

**A grand Nectarine tree.**—In the garden at Gunnersbury House is to be seen one of the most perfect trees imaginable of Nectarine Lord Napier. It has a house wholly devoted to it, at any rate as far as the roof is concerned, and it is to be regretted that this is not considerably larger than it is. The tree covers a roof area 24 feet by 13 feet, and apparently is equal to attaining much larger dimensions. It was planted in October, 1878, in a comparatively shallow inside border, this being only 2 feet deep exclusive of drainage. The stem is about 5 feet high, and I need hardly add stout and cleanly grown, while the branches and head generally are remarkably well balanced. When growing very strongly the fruit buds were shed rather freely by the stronger and medium sized wood, and Mr. Hudson took good care of the spray accordingly, as it was this that gave plenty of very fine fruit. Latterly all the wood bears abundantly, and a more even set of fruit could not well be had. Last summer Mr. Hudson gathered 600 fruits from the tree; this year there will not be so many, but the crop yet appears very heavy. Nearly all are on the upper side where they will colour beautifully, and, as a rule, the Nectarines obtained from this tree are of such a size and colour as to be nearly all equal to taking a prize at first-class fruit shows.—I.

**Apple Fearn's Pippin.**—We seldom hear or read of this admirable Apple, which leads one to imagine that it is not very extensively grown. So far, however, as certainty in cropping, appearance and quality are concerned, I know of few dessert Apples that can surpass it; indeed, I always look upon Fearn's Pippin as being a miniature Blenheim. In appearance it is very similar to that variety, and fruit from the south side of espalier trees colours up most beautifully. It is a fairly good keeper and tells well on the exhibition table. I have grown Fearn's Pippin for a good many years and do not remember once being without a crop. It may be as well to state that our soil is rather light and warm.—J. C.

**Summer pruning of Currants and Gooseberries.**—These trees will repay a little timely attention during this month (June) in the way of pruning useless lateral growth and giving the fruit and wood required for extension room to develop and ripen. Currant trees push out a lot of side or lateral growth. Those which proceed from the main branches and are strong should now be stopped at the sixth leaf. Any growths which break away afterwards should be stopped at the first leaf or joint, as if allowed to grow away they soon crowd up the main shoots and are a prey to aphides and the fruits get dirty, cleansing when in a ripe state being a difficult operation. When the trees have made a liberal growth it is an easy matter to top the main shoots if infested with fly and burn them. By cutting away the tops much of the aphid is removed. Young trees which are required to make a good growth want different treatment, and as it is not well to top too early in their case, I would advise dipping in tobacco water, quassia or other insecticide. One

thorough dipping will often clear the enemy. These trees it very dirty well repay syringing all over, as I notice when crippled in their early stages they rarely make clean healthy growths in successive seasons. Drought will be answerable for many trees being infested with aphid in light soils, and in such a mulch of manure will go a long way in keeping the trees clean. The same remarks apply to Gooseberries, as the trees may now be well lightened of superabundant wood and the fruits much assisted, as by removal of useless lateral growth the main shoots are much strengthened—an important point with weak growers, and by using the knife now there is less sucker growth later on, or when severe winter pruning is practised. Red spider is the worst pest in seasons of drought. Quassia extract is the best preventive used freely in the evening, and if the lateral growths or those not required for extension are removed, the fruits are finer and the trees can be kept much cleaner.—G. WYTHES.

**Shading newly-lifted Vines.**—I think it is a capital plan, and a safe one, too, in cases where old Vines were lifted in autumn to slightly shade the roof glass the following spring, especially if the house is modern and has a sharp pitch, as the Vines often flag in hot, sunny weather until thoroughly established. One lot of Vines came under my notice this season that were lifted last autumn, some fresh material being added to the border and the roots laid in nearer the surface. They broke well in February and grew very strongly, but as soon as hot sun came upon them down they went, not having apparently quite established themselves. This flagging continued for a fortnight in spite of syringings two or three times a day, and although they do not now flag they are much affected with spider. This, no doubt, was encouraged by the strain put upon them during the flagging period. A slight shade thrown over the glass for a time would, I think, have prevented this.—J. C.

#### BLISTERS ON VINE LEAVES.

WOULD you be good enough to state through the columns of THE GARDEN what causes the roughness on the back of the enclosed Vine leaves?—BLISTER.

\* \* I fail to discover anything very seriously wrong with the Vine leaves submitted by "Blister." To all appearances the rusty spots or small excrescences on the under-side of the leaves are the result, first, of the maintenance of an over-moist atmosphere, followed by a sudden rush of cold, dry air. When this treatment—that is to say, a faulty system of ventilation—is continued, the excrescences take the form of warts, and in this case the leaves are seriously injured, failing more or less to perform their functions. The leaves sent are not badly affected and may recover to a more healthy condition. It is just possible the damage to the leaves may have been caused by sulphur on the hot-water pipes or by fumigating with tobacco paper, but I am inclined to believe it is faulty ventilation. It is not such a great amount of air that is needed all during the growing period, as many growers would seem to think. We have had a period of very hot weather, the amount of sunshine and heat registered in May more nearly approaching what we might reasonably anticipate later, or say in July. All the same, there are hundreds of vineries where as yet no front air has been admitted, and that, too, without detriment to the crops, but rather contrariwise. When there is an undue delay in opening the top ventilators the sun's rays cause the temperature in the nearly or quite closed houses to be raised very considerably and suddenly, and the way out of this difficulty that occurs to many is to admit front air very freely, in addition to opening wide the top ventilators. A rush of colder air naturally follows and in its wake various ills, not the least among which is the much-to-be-dreaded mildew, also scalding, chills (considered by Mr. A. F. Barron one cause of shanking of berries), red spider attacks, rust

on the berries, warts on the leaves, "spot," and such like. If by any chance those in charge of a vinery are caught napping, and this may easily happen in the case of those having multifarious duties, there should be no sudden lowering of temperatures. Instead of setting the house wide open, admit the cooler outside air more gradually, and, in particular, guard against a rush through the front ventilators. Better open the doorways at the warmest ends than set wide open the front lights, especially when the wind is in the east. The worst attack of mildew I ever had to contend with was easily traceable to an assistant taking upon himself to open wide the front lights on a bright day in May. At that time they had not been previously opened, and to make matters worse, the wind was in the east and the vinery fully exposed to the full blast of this. What "Blister" and all other Grape growers should aim at is early ventilation, and if this is properly carried out it will be found that injuriously high temperatures will be prevented without setting all the ventilators wide open, while not infrequently little or no front air need be given till the colouring period has arrived. Those who have well studied this question of early *versus* reckless late ventilation can tell by the soft, genial air of a vinery on entering whether or not the ventilation had commenced as early as it ought to have done. It may be asked, how early ought a house to be opened? and this I will anticipate. During still, warm nights a chink of top air may well be put on at 10 p.m., and this be further increased directly the sun strikes full on the house in the morning, or if somewhat clouded, rather before the temperature of the house has risen to the height considered right for the day. A little heat in the hot-water pipes is most desirable. The aim should be to be ahead rather than behind with the ventilating, and if this plan is adopted very much less air need be admitted during the hottest part of the day than is needed where ventilation commences too late. So much importance does one very successful grower of Grapes attach to this early opening of the houses, that those in charge have frequently to open the top ventilators as early as 5 o'clock in the morning, the vineries in this case being span-roofed, and running from north to south, stand high, and get the full benefit of the morning sun.—W. I.

**Apple Golden Spire.**—An Apple that will crop heavily year after year is worthy of the notice of all interested in Apple culture, for, as repeatedly stated in THE GARDEN, we have such a host of practically useless sorts, that any varieties of good quality, profuse in bearing powers and hardy should be brought to the front and their merits placed before intending planters. As a culinary Apple, in season from the beginning of September to the end of November, no variety that I have grown will surpass Golden Spire. With the exception of one year, well remembered by fruit growers for the severe frost about May 20, this variety has not failed to produce a very heavy crop of large and beautiful golden fruit, which no doubt, combined with the conical shape of the Apple, was the means of giving it such an appropriate name. We have many trees in bush, cordon and standard form, and in every case they are remarkable for their prolific habit—in fact, grown as a cordon, no variety is so reliable, the fruit annually setting so freely that a large amount of thinning has to be done, many of the trusses having as many as ten perfect fruit on each truss. Anyone intending to plant only one or two trees, or perhaps as many hundreds, ought to give Golden Spire a trial, and I feel sure they will not be disappointed in the results. As a market Apple I have always found it sell freely at good prices, leaving other varieties like Keswick Codlin, Lord Grosvenor, and Lord Suffield some distance behind in value, and a long way behind in the yield of fruit per tree. Although we have had heavy crops of Golden Spire the last two years, the same trees this season are more thickly set with fruit than ever, proving again the variety's freedom and the immense value of feeding the

trees so liberally with plant food that they are not exhausted with bearing a full crop, but sufficiently strong to continue doing so every year unless prevented by very bad climatic conditions.—W. G. C.

**Strawberry plants killed by grubs** (*P. Hand*).—Your Strawberry beds are badly infested with *Melolontha vulgaris*, the grub of the cockchafer or May bug. The female lays eggs a few inches below the surface in small heaps in one special spot until close upon a hundred have been deposited, the eggs being oval and of a yellowish colour. These are hatched in a fortnight, and when the larvæ are full-sized they subsist upon the roots of various plants. Are your Strawberries planted in recently turned-up turfed land? as if so, the grubs would have been in the soil previous to the Strawberries being planted, and would feed upon the young plants at this season, as they remain in the earth till spring. The best remedies are the following, but you will find winter the best time to get rid of them. When the ground can be turned up roughly and scarified, birds, especially starlings, readily devour the grubs. By using gas-lime freely, digging in deeply, the grubs can be got rid, but of course it is well to allow some time to elapse before cropping if much lime is used. I would advise you to thoroughly work your soil; crop it with a quick-growing green crop and dig it in.—G. W.

## ORCHIDS.

### SMALL COLLECTIONS OF ORCHIDS.

THE increasing number of small collections of Orchids springing up in all directions, not only in the vicinity of large towns, but even in country villages, augurs well for a continuance of the popularity of this favourite class of plants. The frequent auction sales in London have done much towards furnishing these small collections, and most provincial nurserymen now include a few of the better-known kinds in their stock. An occasional sale in a provincial town of plants from a well-known firm has, I know, given a great impetus to Orchid growing in its locality, and the frequent references to Orchids in the press cause inquiries to be made about them. The interest taken in the plants by this class of cultivators is evinced by the nature of the queries that come to hand from time to time respecting their culture, and with a view to aid these beginners in their choice these few lines are penned. The most successful amateur cultivators will be those who, in forming their collections, keep to a few of the best known and easiest grown kinds, selecting them to suit the house they are to be grown in. Thus it is no use trying to grow *Dendrobiums* and *Odontoglossums* under similar conditions, though both are easily grown and essentially Orchids for beginners if arranged in a suitable structure and temperature. If only one house is devoted to their culture I would advise keeping this at a temperature suitable for *Cattleyas*, or a minimum winter temperature of 50°, allowing it to rise in summer to 65° by fire heat, running up to 78° or 80° when the sun is bright. In this temperature it is possible to grow a great variety of Orchids, including some of the most beautiful and distinct kinds in existence, by a little forethought and care in arrangement, and if an ordinary garden frame can be devoted to them in summer, the cool section of *Odontoglossums*, *Oncidiums* and other favourite genera may be included. In a house of this description *Cattleyas* are a host in themselves, keeping up a succession of gorgeous flowers the whole year through. *Dendrobiums* of many beautiful species may also be included, the evergreen section being chosen as far as possible, and

leaving out those that require the strongest heat. There are no Orchids that produce a better flowering return for the room they take up than the latter, and their culture, as noted from time to time in THE GARDEN, is of the simplest description. If there are shady corners to be filled up there are many less interesting Orchids than *Cypripediums*, and some of the most free-flowering kinds in the genus do well in a *Cattleya* house temperature. *Celogyne cristata*, too, is more satisfactory if well shaded, and this is perhaps the most useful Orchid in cultivation. *Oncidiums* are a very interesting class of plants, which cannot fail to be satisfactory under ordinary conditions of culture, their chief requirements being a suitable rooting medium for the various species. The *Marshallianum* and *macranthum* sections are best grouped with the *Odontoglossots* during the summer, but the *crispum*, *Forbesi*, and even *flexuosum* varieties are better for a little more heat. The most frequent cause of failure with all *Oncidiums* is allowing the flowers to remain on too long. The scores of beautiful flowers produced on the long elegant racemes command the admiration of all, and one is loth to curtail their beauty, but if allowed to remain too long, they drain the very life of the plants away, and more havoc is done by one season's overflowering than can be mended by years of judicious culture. The same rule holds good to a certain extent with *Odontoglossums*, and here again for a like reason. These and *Lycastes*, with a few of the better-known *Masdevallias*, are often seen in, and very suitable for, the small collections referred to. In short, there is no lack of beautiful and easily grown species, and in contrast to the high prices now obtained for novel and unique hybrids is the very cheap rate at which these can be obtained. L.

***Cattleya Schilleriana***.—This fine old *Cattleya* appears to be doing much better this season, for I have recently noticed it in fine form in several collections. It varies considerably in the colour of its flowers. It does not appear to have been imported in any large quantities, although it first flowered in the late Count Schiller's collection as far back as 1857. In appearance the growth of this plant much resembles that of *C. Aelandiae*, the bulbs attaining a height of from 5 inches to 6 inches, the leaves deep green above and purplish beneath. It is very rarely that more than a couple of blooms are produced upon a peduncle, and these are usually of a purplish brown on the sepals and petals, with dark spots. The lip is crimson-purple, sometimes striped with a deeper shade, and having a yellow disc. The flowers appear during the summer from the young growths.—W. H. G.

***Cypripedium philippinense*** (syn., *C. lavigatum*) is now in bloom with Messrs. Lewis and Co., of Southgate. This charming little species was introduced through Messrs. Veitch, of Chelsea, about thirty years ago. It grows naturally in one of the hottest parts of the globe, therefore requires plenty of heat under cultivation to grow it to perfection; in fact, it should be placed amongst other Orchids which come from the West Indies and which require as much heat as is allowed in the culture of these plants. It produces three and four blooms upon an erect scape. The flowers, very pretty and graceful, have a white, pointed dorsal sepal, regularly striped with purplish brown; the petals pendulous, narrow and slightly twisted, measuring about 6 inches in length, yellow at the base, changing to a purplish colour, and fringed with blackish hairs. The lip is helmet-shaped, yellowish buff and slightly striped with pale brown. This has proved a valuable kind during recent years to the hybridist, as many of our choice seedlings have this species as a parent. Amongst them may be mentioned *C. selligerum* and its varieties, *C. Vipani*, *C. bur-*

*fordense*, *C. Bryanianum* and many others. It is also closely allied to *C. Rebelinianum*, which was discovered by Mr. Sander's collector in the same locality and which many authorities regard as synonymous; but *C. Rebelinianum* has straighter petals and mostly striped with brown, the scape mere hairy and the foliage much narrower.—W. H. G.

### ONCIDIUMS.

THERE is a wondrous diversity in this very extensive genus, and yet the characteristics are so strongly marked, that one cannot fail to recognise them at a glance. They are all evergreen Orchids of great beauty, and inhabit various parts of South America. Some are large-growing and gross-feeding plants; others are tiny, delicate and close-growing species. The majority have pseudo-bulbs, but there is a section—as represented by *O. Lanceanum* and *O. Cavendishianum*—that are peculiar in these being absent, the plant consisting of large showy leaves upon a thick, hard rhizome. With plants differing so much in habit, varying modes of culture are naturally required, as *Oncidiums*, of all Orchids, cannot in this way be treated collectively. It would take up far too much space to treat at all serviceably of half the species that are worthy, but it may be useful to note a few of the best varieties and species that usually flower at this season. One of the most magnificent *Oncidiums* in cultivation is

*O. AMPLIATUM MAJUS*, the flowers of which are just now beginning to fade after having been open for seven weeks. This superb kind has large, roundish, compressed pseudo-bulbs, bearing very thick and leathery foliage. The flower-scapes are produced from the bases of the newly-ripened pseudo-bulb, and frequently attain a length of 36 inches. Upon these the flowers are plentifully produced, and they are very bright yellow, with a few brownish red spots on the sepals. Being a native of Costa Rica, this plant enjoys a high temperature, exposure to sunlight early in the afternoon, and a moderately moist atmosphere while growing. It may be grown on blocks or in shallow baskets in good peat fibre and Sphagnum, but in all cases care must be taken to ensure a free passage for the water, keeping the plants high and fixing them very firmly. The typical *O. ampliatum* is not so strong-growing or large-flowering as this variety, but is nevertheless a very fine Orchid.

*O. CONCOLOR* is a small, compact-growing Orchid, and one of the most beautiful cool house kinds. It is found growing naturally high up on the mountains in Brazil, and thrives well in shallow wood baskets or suspended pans. The pseudo-bulbs are usually about 1½ inches high, and bear a pair of short green leaves. From the base of these the graceful pendent racemes are produced, and the blossoms are of that clear shade of bright yellow that is so attractive in *Oncidiums*. The treatment often advised for *Odontoglossums* of the cooler section suits this species well, and if kept free from insects and in good condition at the root it never fails to flower freely. It is one of the most frequently exhibited Orchids, excellent for grouping.

*O. CURTUM* seems to have been brought from Brazil in 1846, and thrives in more heat than the last-named kind, being most satisfactory in the *Cattleya* house. It is very impatient of closeness at the root, and for this reason must have a thin layer of compost only. The pseudo-bulbs occur on wire-like rhizomes, and the flower-spikes are erect and dense. Each blossom measures about 1½ inches across, and is yellow, with reddish brown spots.

*O. FLEXUOSUM* is a very common Orchid, but one of the most useful and beautiful kinds in cultivation. For cutting there is hardly another species to compare with it, as the spikes, owing to their light, graceful appearance, can hardly be wrongly placed, working up well for all purposes.

This is usually grown too cool to get the best results and in too close a compost. Grown in a shady part of the Cattleya house in Sphagnum Moss and charcoal alone, it makes a wonderful growth, the spikes being very long and plentifully produced, as many as four from one pseudo-bulb not being at all uncommon. The flowers are too well known to need description and the plant is a native of Brazil, whence it was introduced early in the present century. The variety *majus* is larger than the type and the flowers more freely spotted.

*O. GARDNERI* is a very fine species of the *crispum* set, and very like *O. Forbesi* in general outline. The colour is bright yellow and brown, the latter predominating on the sepals and petals, the lip beautifully margined with the same colour. This may be grown in a cool, airy part of the Cattleya house, suspended near a ventilator if possible, on a trellised raft, with a little peat fibre and Sphagnum. Introduced from the Organ Mountains, in Brazil.

*O. PAPILIO* and *O. KRAMERIANUM* may be bracketed as far as treatment is concerned, they being simple varieties of the same species, though perfectly distinct. The latter is the deeper coloured form, and both are remarkable for the striking resemblance they bear to a butterfly. They thrive best in a strong, moist heat and require very little compost about their roots, Sphagnum Moss being the chief ingredient. The wiry peduncles rise from the base of the pseudo-bulbs and bear one flower at a time, these being produced at intervals all through the summer and early autumn. The frequent flowering ultimately weakens the spikes, as shown by the smaller blossoms produced; and when this is observed the old spikes should be cut off, when fresh vigorous ones will soon form. *O. Papilio* and its varieties are natives of the West Indies and have long been cultivated in this country, having been introduced in 1823.

There are several other species now in flower, but these will suffice for the present, and other deserving kinds will be noted as they come into bloom.

R.

#### DENDROBIUM FALCONERI.

This has been grown in our gardens for about forty years, and was at one time frequently seen at our large exhibitions. This year at the Temple show it was only represented by a single example, which was included in the collection staged by Mr. James Cypher, of Cheltenham. This plant was both well grown and well flowered. *D. Falconeri* succeeds best when grown upon a block of wood or attached to a piece of Tree Fern stem, and as it is a native of Northern India, coming from Assam, Bhotan, and the Khasia districts, where it grows at less than 4000 feet altitude, it will succeed best when placed close to the glass in the East India house, and where it should be liberally supplied with water during the growing season. After the growths are finished a slightly cooler temperature and less moisture will suffice, but care should be taken that the plants do not suffer from drought during this resting period. This fine Dendrobe produces long slender pendulous stems, which are knotted at short intervals, and carry a few small leaves upon the new growths. The bulbs emit roots along nearly their whole length, which gives the plant a curious appearance. The flowers, which appear singly from the leafless stems, each measure between 2 inches and 3 inches in diameter, the sepals and petals white, faintly flushed with rose, the tip of each being blotched with rich purple; the lip is also white, with a large central maroon blotch, a bright yellow spot on each side, and the tip purple as in the sepals and petals. It seems to have first appeared amongst a batch of mixed Orchids from India, but since it has been im-

ported in quantity some distinct varieties have come to hand, the best being

*D. FALCONERI GIGANTEUM*, which in every way resembles the typical form, but produces larger and stouter pseudo-bulbs. The blooms are upwards of 5 inches in diameter, of better substance, and deeper in colour. This form, I believe, first appeared in Messrs. Veitch's nursery at Chelsea.

*D. FALCONERI ALBIDULUM* first flowered in the gardens of Mr. H. Elliott, of Clapton, several years ago. It has blooms entirely white, except a slight tinge of rose at the tip of each segment. There also appears to be what is known as a blunt-petalled variety, which only differs from the typical form in having the petals quite oval instead of tapering to a point. This is a free-flowering and very desirable kind, as its blooms open during the months of May and June, and will continue in perfection for about a fortnight.

W. H. G.

#### NOTES ON PHALÆNOPSIS.

Nothing could have suited these lovely Orchids better than the tropical weather of the last few weeks, the plants growing most freely in the atmosphere, quickened, so to speak, by the action of the sun. Moisture in abundance, both at the root and in the atmosphere, has been necessary, but this is easily applied and can hardly be overdone just now. This quick growth is just what is required now, and the plants will rapidly pick up all they lost by the long cold winter. On dull, misty mornings, which are precursory to hot days, the ventilators and even the doors may be left open without the least fear, as this causes a natural rise in the temperature instead of an upward rush as the sun reaches the house. All tropical Orchids delight in this, and none more so than Phalænopsis. If a *Dendrobium* or similar plant grows too quickly and with a want of solidity, it is comparatively easy to remedy this by exposure in autumn, but this will not do for the Orchids under notice. The growth must be consolidated as it is made, and if this is the case it does not matter how rapid the progress is. Ventilate freely then in early morning and keep closer and shaded in the middle of the day when the outside temperature is high and the atmosphere parched. A little more ventilation just before closing time may be given and the blinds drawn up about an hour before the sun leaves the house. Plants that were repotted about six weeks ago are now rooting freely in the new compost. These require an increased supply of moisture at the root, and those showing flower-spikes are very carefully watched and the number of flowers restricted as they become visible. The strong-growing kinds are watered almost daily and occasionally lightly dewed with soft tepid water. *P. Luddemanniana* is doing well in small wood baskets, the charming blossoms, so delicately spotted with violet and purple, being now on the wane. Several young plants of this species are now in a 3-inch pot, whence they are to be transferred to small baskets. Never allow insects to gain the least foothold on the plants, as sponging, unless very carefully done, is very injurious by puncturing or bruising the foliage. For this reason soft water must always be used, as the hard water leaves a deposit on the leaves that requires some force to remove, and is, in the case of water from a chalky soil, injurious to the roots. If the temperature can be kept up to about 60° without fire-heat this need not be used at night, but on dull days a little warmth must be kept in the pipes to admit of ventilation and prevent any check to the plants.

R.

*Laelia majalis*.—I was glad to see "G." giving the foremost place among the Mexican species to this superb kind, which is quite worthy of all the praise he bestows upon it. That it is difficult to flower I can hardly agree with, as no Orchid flowers more constantly with me. The only thing necessary is a thorough ripening of the pseudo-bulbs, and the best way to do this is to

place the plants in the open air as soon as the growth is finished. If anyone who finds a difficulty in flowering it treats it in this way, other conditions being suitable, there need be no fear of the result. A plant in a 5-inch pan here has borne three twin-flowered scapes this season, although it flowered twice last year owing to a slight error in management. I quite agree with "G." that this and, in fact, all the species he names greatly dislike disturbance at the root, and for this reason repotting must be very carefully done.—H. R.

#### ORCHIDS ON FERN WALLS.

There are often many unsightly places in Orchid houses that puzzle those in charge to cover so as to make them look bright. Ferns and various fine-foliaged plants, such as *Begonias* of the *Rex* type, *Tradescantias* and others, are usually the plants selected, but a very welcome addition to this may be had by using a few Orchids of suitable kinds. For these it is obvious something in the way of special preparation is needed, and if a little care is given to this, very pretty effects may be produced. I once had occasion to cover the back wall of an *Odontoglossum* house, the owner wishing to try the experiment of growing Orchids in conjunction with Ferns, and although I must confess I was rather doubtful of success, the results were much better than I anticipated. The wall in question was 9 feet high, and there was a narrow border that had been used for *Roses* running parallel with it. This was taken out to a depth of 18 inches and 15 inches of rough potsherds and broken bricks substituted, and as the soil was of a light gravelly nature, this formed an efficient drainage. An undulating line of rockwork was placed on this, the upper portion being planted with *Pteris tremula*, *P. serrulata* and *Adiantum capillus-Veneris*. The bays left were filled with a rough mixture consisting of loam, turfy peat, Sphagnum, and potsherds, and in this were planted some pieces of *Cypripedium insigne* out of 8-inch and 9-inch pots. The plants were not kept on the level, but raised a few inches, the compost being banked round them, and the small green *Tradescantia* was allowed to run over this. The upper portion of the wall was wired with netting (2-inch mesh) and the Ferns planted in the usual way. Some suitably shaped pieces of cork were arranged in various positions to form receptacles for the Orchids, and the Ferns encouraged to hide this as far as practicable. *Celogyne cristata* and *Oncidium macranthum* were the Orchids principally used, with a few crowns of *Disa grandiflora* near the bottom. All these did well, but *Oncidium Marshallianum* was a failure. The pockets of cork were filled with the usual compost, especial care being taken to provide good drainage, and as the *Celogyne* outgrew its station the Ferns had to give way. There is possibly nothing new in this mode of growing Orchids and Ferns in conjunction, but I mention it that those who may be similarly placed may try the experiment in confidence. Possibly many other species would be suitable, and doubtless very pretty effects may be produced in a warm house where *Cypripediums* in variety may be used at the base, these Orchids having a very natural and striking appearance when viewed from above. Some growers may be inclined to favour brackets in similar positions to the cork pockets, placing the plants thereon when in flower, and in that way beautiful effects can be obtained—in fact are in more than one well-known nursery, to say nothing of private establishments, but the plants can never have the same easy, graceful appearance as they have when growing in the natural manner alluded to above.

R.

STOVE AND GREENHOUSE.

WATER LILY HOUSES.

THE engraving of the little Water Lily house at Castlewellan, Co. Down, is from a photograph specially taken for THE GARDEN by the Countess of Annesley. The house itself is really a warm plant stove, having a tank for the Nymphaeas, fringed with velvety-leaved Aroids and feathery Palms. The water in the tank is refreshed by the spray of a fountain, that also makes soft and pleasing music as it drops among the leaves and flowers. As so grown, the new and beautiful hybrid Nymphaeas of M. Latour-Marliac are nearly evergreen and almost perpetual in their bloom—white, rose, crimson and soft yellow. The waxy and, in some cases, sweetly odorous blossoms open morning after morning

shades of rose and pale yellow, white, and even dark crimson. M. Latour-Marliac's best seedlings and hybrids are exceedingly robust and beautiful, and they enable us to obtain somewhat of the effects of tropical Water Lilies in the open air, and even in cold water ponds or pools. Mr. Greenwood Pim, of Monkstown, who formerly had no water garden, overcame the difficulty by simply making a concrete tank of irregular outline and 18 inches deep in an open, sunny portion of his garden. It is in full sunshine and its margins are rock-fringed; thus a suitable position for many interesting alpine and bog plants is also obtained. In this little sheet of water only a few yards square there is just now quite a profusion of flowers, mostly of good forms of *N. alba*, but five or six of Marliac's rosy crimson and sulphur-flowered hybrids are also there, and probably now in bloom. In this sun-warmed water the common

for a new and improved house for aquatic plants, and those who have had the privilege of visiting Baroda House at Kensington have been delighted by the Water Lily gardens under glass that are there to be seen. The advantage of a glass-roofed tank is the longer season of blossoming that it enables one to enjoy, and even the most tender of tropical species, such as *Victoria*, *Euryale*, and *Nelumbium*, may be grown for six or eight months of the year minus any heating apparatus except that of the sunshine itself. At Daisy Hill, Newry, Mr. Smith has a very simple and efficient span-roofed house for Water Lilies, *Sarracenias*, *Darlingtonias*, and other fly-catching plants that is always a pleasure to see. It is simply a span-roofed house with a central walk, the tanks being about 18 inches deep, close up to the level of the eaves, and occupying all the remaining space. Here all the forms of *N. Marliacea*, *N. Leydekeri*, *N. odorata*, *N. pygmaea*, and *N. Helveola* grow and bloom in the prettiest possible way. Early in May *N. Leydekeri* opened its deep rosy-crimson petals, and one or other of M. Marliac's seedlings and the wild species will produce flowers in profusion until the waning days of autumn, after which the tanks can be covered with boards, and then become a shelter for other things.

Here in the College Gardens our first flowers did not open this year until June, and then *N. alba*, *N. pygmaea*, *N. Leydekeri*, *N. Chromatella*, and *N. carnea* all raced each other for precedence. This pond is about 4 feet deep, and is fed with cold water from the Dodder River, and for six weeks last winter it was covered with ice often to a depth of 8 inches, and yet neither Water Lily nor gold fish, of which there are some hundreds, suffered the slightest injury. The illustration only shows the indoor phase of Water Lily beauty at Castlewellan, for these flowers are largely grown there in open-air lakes and ponds as well as under glass, and there is every prospect of that noble demesne becoming as famous for its water plants and water-side vegetation as it now is for its magnificent trees, shrubs, and wall climbers, amongst which last may be mentioned some fine examples of *Vitis Coignetii*, one of the handsomest of foliage plants from Japan. The Earl of Annesley has long grown this noble species of *Vitis*, and many plant lovers are deeply indebted to him for his liberality in sharing with them his choicest rarities. F. W. BURBIDGE.

A Water Lily house at Castlewellan. Engraved for THE GARDEN from a photograph sent by the Countess of Annesley.

or evening after evening for at least six or eight months of the year. Beautiful and fresh and sweet always are these delicately modelled flowers, especially as seen in happy association with rarest of Palms and Ferns and the most delicate of foliage plants, for at Castlewellan the artist and the gardener work in unison. There are more than one or two ways of growing the choicest of hardy Water Lilies, however, but the advantage of a glass house is that the blooms are earlier and fresher, and a view of them is more easily obtainable at close quarters than when they float in the deep water of an open-air pond or pool.

Formerly we were confined to very few hardy Nymphaeas, and these mainly the white and rose-tinted forms of *N. alba*, but of recent years—thanks to collectors and hybridisers—we have at least twenty good hardy kinds of nearly all

white Water Lily blooms at least eight to ten days earlier that it does in deeper water, and there is the advantage of being able to look at, or to gather the ivory blooms without the slightest inconvenience. Thus at a cost of a few shillings for cement and other materials, and a clever labourer, anyone can make a pretty and practical tank for these most exquisite of flowers.

Wherever there are tanks indoors in warm plant houses the tropical species are readily grown. At Kew for years the tank in the old *Victoria* house has been jewelled with Nymphaeas and other aquatics, and the same is true at the Oxford and Cambridge Botanic Gardens and at Regent's Park. At Birmingham, where they have just inaugurated a very beautiful new rock, alpine and bog garden in memory of the late Mr. Hugh Nettlesfold, there is a project

**Stigmaphyllon ciliatum.**—This has very appropriately received the common name of Golden Vine. It is a stove climbing shrub, a native of Tropical America, of somewhat tall growth, the shoots of which are trained horizontally under the roof of the large Water Lily house at the Birmingham Botanic Gardens. The flowers are yellow, three to six in an umbel, and curiously clawed. It appears to bloom freely, and is just now an object of considerable interest. A figure of this plant was given in THE GARDEN for Feb. 25, 1888, p. 170.—R. D.

**Flowering Cacti.**—For the last few years Messrs. Veitch have identified themselves with a very free-flowering race of *Phyllocacti*, and most years some members of this section are recognised by the Royal Horticultural or Botanic Societies, while a small group of flowering examples is now regarded as one of the features of the Temple show. This year one variety—Excellent—received an award of merit. It is very distinct, the colour of the flower being a kind of warm orange-salmon, shading off to red towards the margins. Other varieties particularly noticeable were *Agatha*, soft pink; *Brilliant*, vivid scarlet; *Rowena*, bright crimson; *Gordonianus*, pink; *Jessica*, rose; and a beautiful white flower, which was without a name, but it seemed to be much

Cecilia. Well worthy of a place among the most select of this group is the variety J. T. Peacock, which is a form of the old P. speciosissimus, itself such a favourite with our forefathers. The striking violet lustre which overspreads the petals is in J. T. Peacock much more pronounced than in the older form, and few flowers have so brilliant a colouring. These different Phyllocacti are of very easy culture, for given an ordinary greenhouse anyone may succeed with them. A soil principally composed of loam with an admixture of sand and brickmakers' ballast or sandstone rubble will suit them perfectly. Over-watering must be especially guarded against, for though they may be kept pretty moist during the summer months, yet at the dull period of the year from their succulent nature they will stand a good while without water. A light, sunny spot in the greenhouse is also essential to their well-doing, for upon the thorough ripening of the wood resulting from full exposure to sunshine and careful watering during the dull season depends to a great extent the future display of bloom. Propagation of this class of Cacti is readily effected, for if a piece is broken off, potted, placed on a shelf in the greenhouse, and watered occasionally, it may be depended upon to root. The better class of flowering Cacti are, I think, increasing in popularity, and to the amateur with but little time (and that of an intermittent nature) to attend to them, they possess a great advantage over many other classes of plants.—H. P.

**Gloxinias.**—Judging by what has already been seen this season, there seems to be danger lest raisers of these flowers should make the same mistake that has been made with Begonias—that is, in seeking for such huge flowers. This rage in the Begonia bids fair to destroy that flower in popular estimation. The Gloxinia has blooms large enough for any purpose. Larger flowers will look coarse. We have almost everything that can be desired in habit and in freedom of flowering. We have, too, excellent size and form in the flowers. The chief need is in greater variety of colours and markings, and specially the introduction of more soft, refined hues, also in making the flowers stout and of the best form. Beautiful as are the forms having defined edges, it is possible to render them in that direction too formal. Generally self-coloured flowers are best.—D.

#### PLANTING OUT CALLAS.

We often read how successful some cultivators are with these plants who rely upon planting out. Doubtless much of the success is due to attention after planting, careful lifting in the autumn and other cultural details. So far I have secured the best results by a combination of the two methods usually adopted, and find I get much earlier flowers by potting and plunging the pots well over the rims during the growing season. When the plants are housed in the winter the pots are full of roots, and they flower much sooner than lifted plants, which have to make their new roots before they flower, a check being unavoidable when potting up. It may be urged that plants with a mass of healthy roots soon make new growth, but as the potting does not take place till September—often later in open weather—growth at that season is not so rapid as earlier, and I find it impossible to do the work, no matter how carefully lifted, without loss of some leaves and roots. The earlier these flowers are produced in the winter months the more valuable they are. At Christmas Calla flowers are most useful in room or church decoration, and they are none too plentiful at that season if the plants are potted up late, as even if forced they do not flower freely and give small blooms. With a deficiency of large flowers in mid-winter the Calla is one of our most useful plants, as five or six blooms in a large vase with a few leaves is an effective arrangement that lasts a long time in perfection. My mode of culture to obtain early blooms is simple, and may be interesting to those who grow these plants. At the end of June we turn all old flowering plants out of their pots, the plants having been rested

for a short time in the open by giving them less water. Each plant is divided, removing side or sucker growths, selecting the largest pieces, as these are the most valuable, and the next size for succession. The small ones are not often required, as the plants increase so rapidly. Each plant is potted singly and firmly in good loam, bone-meal, and either spent Mushroom manure or leaf-mould, well watered and plunged, covering the rims in trenches or deep drills for convenience of watering the plants during growth. As the new leaves push up towards August liquid manure is given freely and the plants watered overhead in the evening daily as they increase in growth. They are housed in September, and given more warmth early in November, they flower freely when placed in a temperature of 55° to 60° certainly better than when grown in the old way.

G. W. M.

**Vallota purpurea in flower.**—We are so accustomed to see *Vallota purpurea* flowering towards the end of the summer or early in the autumn that blossoms of this showy bulbous plant (during the month of May appear somewhat out of place. Such a result is, however, frequently attained now-a-days, not from any forcing or particular treatment that has been brought to bear upon them, but owing to the fact that great numbers are now sent to this country every year from their South African home, and they reach here totally dormant about the months of July or August, when if they are at once potted and kept slightly moist they continue to root throughout the winter, and on the return of spring the foliage is pushed up in a very vigorous fashion, and many of them will then flower. This precocious habit is only noticeable the first season, as the following year, though perhaps a few of them will bloom rather earlier than the normal season, in the majority of cases there is little difference. These imported bulbs need very careful treatment for a year or two, as they do not readily become established. The most critical period I find is the second winter that they pass in this country. During the first one they are, of course, quite dormant. They do not yield so good a type of flower as the old-fashioned form, so long cultivated in gardens, for the flower-stem is much longer, the flowers as a rule more star-like, while many of them are poor in colour. Flowers of a distinct salmon shade sometimes crop up among imported bulbs, and a white variety is spoken of, but it has never been my fortune to meet with this.—H. P.

**New Fuchsias.**—The Fuchsias distributed by that well-known raiser, Mr. Lye, are characterised by a great profusion of, in most cases, medium-sized symmetrical-shaped blossoms, but though these varieties are well known in the south and west, they are not so generally met with in other parts of the country. I am not aware if Mr. Lye has sent out many new forms within the last four or five years, but the bulk of the novelties come from the Continent, and large blooms with, in many cases, an ungainly habit of growth form their most prominent feature. Nearly all the new forms from the Continent are double-flowered, and though opinions may differ as to which are the more beautiful, the majority would, I think, be in favour of the single flowers. The double-flowered varieties consist of in many cases a huge corolla and sepals far too short to form a proportionate flower, while they are often disposed in a horizontal manner instead of being reflexed, as in most of the old single varieties. As Fuchsias are so readily raised from seed, it is somewhat singular that they are not more often increased in this way, for with a little care in saving the seed some good flowers can be counted upon, while at times curious forms crop up, and a very desirable new variety may also appear.—H. P.

**Pelargoniums in London.**—A great deal of the beauty of a Pelargonium consists in the foliage being retained in good condition till the flowering season, for if bare of leaves at the base, a plant, however fine the flowers may be, loses a good deal

of its attractiveness. A considerable amount of care and attention is necessary to grow these plants at their best, and the atmospheric surroundings play a very important part in the matter. So pronounced is this that it is now quite impossible to grow Pelargoniums as near London as they could be grown a few years ago. This remark applies also to other classes of plants, hence our market growers, who well recognise the value of a pure atmosphere, push farther and farther from the metropolis. In addition to the Pelargoniums the Bouvardias are a class of plants greatly injured by the smoke of London. The difficulty is not of course during the summer months, but in the autumn and winter when fogs prevail. At that season the plants are in a state of semi-darkness for days together, and that in conjunction with a sulphur-laden atmosphere will cause the leaves to turn yellow and drop. In this way I have seen a house of plants reduced from a flourishing state to little more than bare stems within a week. A free circulation of air is very necessary to the welfare of the Pelargonium, and so apparent is this that I have seen plants even in the summer lose a great many of their leaves after being packed up for a day or two and sent on a journey.—H. P.

#### PLANTS AT GUNNERSBURY HOUSE.

SCENTED Pelargoniums are remarkably well grown by Mr. Hudson at Gunnersbury House. One set of above a dozen plants, which have taken from four to six years to grow, are now each fully 6 feet through, and stand nearly as much in height. They are in neat, durable, circular tubs 17 inches across and the same in depth. These tubs are well pitched inside, a precaution that ought always to be taken, while outside they are oak-grained, and the bands and handles painted black. These charming old-fashioned, yet uncommon plants, as grown at Gunnersbury House, are really serviceable, as a few weeks' or months' service in their owner's town house and grounds appears to benefit them rather than otherwise. The species or varieties that lend themselves most readily to this form of culture are quercifolium, or the Oak-leaved variety; the old Pheasant's Foot (*radula* major), which is Citron scented; *filiolium* odoratum, and capitatum, this latter having Rose-scented foliage. In addition to these fine globular trained specimens Mr. Hudson has also grown some remarkably fine screen plants which are unique in their way. The variety selected for this method of training is *radula* major, and the plants of this are 6 feet high and over 8 feet through. They are in tubs similar to those already described, and according as the plants extend, a semi-circular width of trellis-work is added. I also saw a number of half specimens not only of the varieties named, but also of *quercifolium* minor, *Rollisson's Unique*, scarlet unique, *denticulatum* majus, *Pretty Polly*, fragrans or nutmeg scented; *Fair Ellen*, and *Little Gem*, all of which have scented foliage and in some instances attractive flowers. The soil used is Banstead loam and leaf soil, sulphate of ammonia being given as a manure when the pots are well filled with roots. All are cool greenhouse plants.

Trained sweet-scented Verbenas are appropriate companions for sweet-scented Pelargoniums, and of these there are a series of standards at Gunnersbury House that reflect the greatest credit on the grower. They were struck four years ago, and are grown with a clear stem, the heads being trained in the form of shields, urns, and such like. Trained *Marguerites* (*Chrysanthemum frutescens* varieties) were also fine, these likewise being intended for the town house. They were struck in January, 1894, and are now perfect globular specimens 6 feet through. These are in terra-cotta vases, and are already flowering grandly. Young plants are constantly being brought forward to take the place of the older ones, the former producing the finest flowers in the greatest profusion. They are kept free of the much-to-be-dreaded leaf-mining maggots by means of Richard's vapouriser, of which Mr. Hudson has

formed a very high opinion. Yet another old-fashioned plant that is here grown to perfection principally for town house and garden decoration is the small or Box-leaved Myrtle. These plants naturally assume a free pyramidal form, and are about 4 feet in height. They are flowered twice in the year. When I saw them in May all the points of the growth made last season were full of flower-buds, and the second crop of bloom will be had next autumn from the current year's growth. The plants were layered rather more than four years ago. They are most ornamental, and suitable for lawn, drive, and terrace decoration. W. I.

## FLOWER GARDEN.

### LILIUM ELEGANS.

This lovely Lily, so varied in form, colour, and stature, is an early flowering species, and its several varieties could be used in the garden in a variety of pretty ways, perhaps the best of

of striking colour; robustum, orange-yellow, spotted with crimson; sanguineum, deep red; Van Houttei, crimson, flamed with apricot, and spotted with black; Wallacei, spotted orange-red; and Wilsoni, of a rich apricot tint, and one of the latest to flower.

### FLOWER GARDEN NOTES.

VIOLAS are undoubtedly at the present time furnishing a brighter display than any other dwarf-flowering plant, and this despite the fact that from the commencement of flowering to the present date (June 7) the weather has certainly not been of the nature universally regarded as most conducive to their well-being. They are altogether immeasurably better than at the same time in 1893, when a similar dry spring was experienced; this, however, may be partly explained by the heavy rains of last winter and the ground being comparatively moist close under the surface. Also with the brief flowering season of 1893 always in memory I have since before planting in autumn dug in a fairly liberal dose of cow

*Lilium elegans.* From a photograph sent by Miss Willmott, Warley Place, Essex.

all in association with choice dwarf-growing shrubs. Among low evergreen shrubs or in little groups in the foreground these Lilies would find an admirable setting to bring out their rich colour effect. We should have more of this blending of flowers and shrubs in our gardens instead of allowing the shrubs to grow into a dense, confusing tangle, and setting out all the flowers in the full glare of the sun in prim beds and inartistic borders. There are quite a dozen distinct kinds, some of them only 1 foot or even less in height, others ranging up to 3 feet or more. They like sunny situations, and grow well in loamy soil. The type grows about 1 foot high, and has orange-red flowers quite 6 inches across. Alice Wilson has flowers of a bright lemon-yellow shade and is very distinct. It was figured in THE GARDEN of November 8, 1890. Alutaceum grows about 1 foot high, with flowers of a soft apricot-yellow shade, and Batemanniae, one of the tallest, has fine bright apricot flowers. Other handsome sorts are bicolor, orange-red flamed with scarlet; eruentum, deep blood red

manure, a proceeding that would be unnecessary on stiff land that retains moisture well, but that is highly beneficial and, indeed, almost indispensable when dealing with our light, dry soil. The chief drawback experienced in very dry seasons is the non-retention of colour in all pale shades in mauve, lavender, and lilac, and also in those flowers that combine a couple of shades in regular marking, as, for instance, Duchess of Fife. If at the present time I were to pick a couple of the most distinct and the most dissimilar flowers on Annie King, Lilies, William Niel and Blue Cloud, it would be hard in either of the four cases to convince anyone that the two blooms came from the same bed, except from some special characteristic in the eye, or the shape, or make of flower. This failure to retain the true colour is rather a difficulty when one is shading the varieties down in considerable quantities, but otherwise is in no way detrimental to the general appearance of the beds, except that one is not getting for the time being exactly what they bargained for. The fact that several new seedlings of the Kintore type are now being annually produced has suggested the advisability of classing them alone as, I believe, bedding Pansies. They are no doubt

capital varieties for large beds, flowering as freely and with as long-sustained effect as the Violetta type, although their habit is so different to the last-named, the power of reproduction by division into scores of shoots, each with its tiny complement of roots, being practically absent.

COMPLETION OF PLANTING.—Any plants remaining over after the planting of the flower garden proper can, if they are suitable for the purpose, be used for filling up bare spots that may exist on herbaceous borders or for shrubberies that may be rather thinly planted. A few plants of the large-leaved and of the Sweet Tobaccos are useful for such work, and if birds have made havoc of any rings of Sweet Peas (and it is no uncommon occurrence), plants remaining of Canary Creeper and the variegated Hop can take their place, a very pretty effect being produced by the pyramids of flower and foliage. Seented Pelargoniums are always acceptable, and a few clumps of these are by no means out of character with the permanent inmates of the borders. I also found last year occasional clumps of the Begonia semperflorens family furnish both in the matter of flower and foliage an admirable background to masses of dwarf silvery edgings. Where clumps of bulbs, as Hyacinths, Daffodils, &c., exist on herbaceous borders, the ground will soon be bare of foliage, and it is advisable if possible to save enough dwarf stuff in the way of dwarf Petunias and Lobelias, Mesembryanthemums, &c., to furnish the same. It may be noted that when planting anything in the way of annuals (whether naturally so or which from their tender constitution have for outdoor work to be classed as such) on herbaceous borders, it is always advisable to so regulate such planting that the temporary plants harmonise with their immediate surroundings. Thus the single small-flowered annual Sunflower should not find a place beside its perennial allies, but as a background to, say, early flowering Phloxes, Lychnis, &c., and the fine-foliaged Cosmos, which will come early into flower if planted in good time, may be used to brighten up a space between clumps of autumn-flowering Starworts. A few clumps of Dahlias, free-flowering Cactus varieties as Fire King, Panthea, and Constance for choice, will also prove acceptable to fill up gaps towards the back of borders; these can be planted rather close to clumps of early flowering Lilies, whose flower and foliage are over comparatively early in the season, causing somewhat unsightly gaps. *Aprropos* of Lilies, the old *candidum* is likely to be very fine this season: the flower-stems are very strong and vigorous and the foliage as yet free from disease. Beds that are partially filled with small Conifers as dot plants for a carpet of flower are quite at their best now, the silver and gold-tipped growths on Thujopsis, Thujas, Retinosporas and one or two Cupressus being very pronounced and beautifully clear and fresh. There are few better dwarf plants to be used in connection with the Conifers than Violas, and, once planted, they give no more trouble than the prompt removal of dying flowers. I have also, in lieu of the Violas, used a dwarf strain of Antirrhinum in crimson, yellow and white shades, and the effect somewhat later in the season is very pleasing. The Conifers should be kept within bounds by the judicious use of the knife, nothing, of course, in the way of clipping or shearing, but the removal of ragged shoots and the shortening of any that are inclined to go away to the prejudice of the plant as a whole, the object being to keep at once a symmetrical, dense, and yet natural specimen. In connection with the notes above on the filling up gaps in herbaceous borders with the more tender summer-flowering plants I may add that, as mentioned in the case of Lilies, it is always advisable to plant comparatively close to those things whose flowers are quickly over and that do not retain their foliage; or if the latter is retained, it has not a very presentable appearance for the remainder of the season. I like to make an herbaceous border as natural as possible by bold and judicious planting, but am by no means in favour of following Nature to the extent of allowing dead and decaying foliage to remain on the plants; indeed, in all cases where such borders

occupy a prominent position in gardens the practice could not be tolerated. E. BURRELL.

Claremont.

A SELECTION OF ORNAMENTAL HARDY BORDER PLANTS.

We are frequently asked by readers for lists of hardy and other plants, and we therefore offer no excuse for printing the following list, which contains what we regard as the best of the true herbaceous plants. Our aim has been to make a selection of the most reliable hardy flowers adapted to the soils and situations of gardens generally. No one can desire less than ourselves to limit the variety of plants of this sort, but a great deal depends upon whether a successful beginning is made in this way, and the following is a choice selection of plants upon which growers can depend, and which can be successfully cultivated in most districts. It should be borne in mind that, restricted as this selection is, there are whole classes of important hardy plants not included in it—for example, hardy bulbs, alpine and rock plants, and, lastly, biennial plants and plants which, like the Carnation and some of the double Rockets, require annual division or multiplication for successful culture.

- Acanthus spinosa
- Achillea Parmica fl.-pl.
- The Pearl
- Eupatorium
- Millefolium rosea
- mongolica
- Aconitum Napellus
- bicolor
- japonicum autumnale
- Adonis vernalis
- Astromeria aurantiaca
- Auemeone japonica
- Honorine Jobert
- Pulsatilla
- patens
- coronaria, many vars.
- alpina
- fulgens
- Robinsoniana
- sylvestris
- Anthericum Liliastrum
- Liliago major
- Aquilegia vulgaris and vars.
- chrysantha
- californica alba
- coerulea
- glandulosa
- Stuarti
- Armeria cephalotes
- grandiflora
- Arnebia echinoides
- Aster Amellus
- levis
- acris
- linearifolius
- Shortii
- turbinellus
- versicolor
- horizontalis
- Novi-Belgii vars.
- Bocconia cordata
- Brodiaea Howelli
- Calochortus in var.
- Caltha palustris and vars.
- Campanula Van Houttei
- nobilis and vars.
- celticifolia
- glomerata
- dahurica
- urticaefolia fl.-pl. alba
- carpatia and vars.
- grandis
- sophylla alba
- persicifolia and vars.
- Cardamine pratensis fl.-pl.
- Centaurea montana and vars.
- Centranthus ruber and vars.
- Cheiranthus
- Chelone (hybrid vars.)
- Chrysanthemum latifolium
- maximum
- indicum, good outdoor kinds
- Cimicifuga racemosa
- Coreopsis lanceolata
- grandiflora
- Coronilla varia
- Corydalis nobilis
- Cypripedium spectabile
- Delphiniums in var.
- Delphinium belladonna
- Delytra spectabilis
- Digitalis (Foxgloves)
- Dodecatheon Meadia and vars.
- Doronicum in var.
- Echinops Ritro
- Epilobium Fleischeri
- angustifolium
- album
- Epimedium macranthum
- superbum
- Eremurus robustus

- crassifolia
- cordifolia and other vars.
- longifolia
- pyramidalis
- Scabiosa caucasica
- Scutellaria alpina and vars.
- Sedum spectabile
- Senecio pulcher
- Sidalcea candida
- Spiræa palmata
- Aruncus (good vars.)
- Filipendula fl.-pl. japonica
- venusta
- Statice latifolia
- Symphytum bohemicum
- caucasicum
- Tiarella cordifolia
- Tradescantia virginica vars.
- Trollius asiaticus
- Fortunei
- europæus and vars.
- Veratrum nigrum
- album
- Verbascum phlomoides
- Chaisi
- olympicum
- Verbena venosa
- Veronica candida
- corymbosa
- longifolia subsessilis

NOTES ON HARDY PLANTS.

**Umbilicus spinosus.**—I wonder if it will be credited that this is really quite hardy—hardy to the extent implied by plants fully exposed all the winter of 1894-95. Generally, I believe, this neat and curious plant has been considered to need protection in even ordinary winters, and I have always made a point of placing it in a frame as soon as the fogs begin in October. I had, however, a good stock last year, and I purposely left out three specimens. All are now in good health, even one that was badly grazed by slugs in the autumn. If this succulent sometimes fails to stand our winters, it is not merely owing to the cold, for my plants must have several times had frost on them within 2° of zero.

**Aletris farinosa.**—In the same very similar conditions to the above as to aspect, a specimen of this has much surprised me by coming through the winter safely; it is at the base or moister part of the rockery, and not only is it not hurt, but it is now throwing up flower-spikes. The plant is a two-year acclimatized specimen.

**Hypericum balearicum.**—I never could keep this even in mild winters. I was induced to try it repeatedly because I heard from garden

friends how well it did and that it survived the cold, so on the chance that such a singular and beautiful species might be coaxed I often tried it, but it went off at the end of summer. A friend in Wales told me early this spring that his plants, though injured, were pretty safe. Many of us, however, have learnt to put little or no trust in the appearance of some plants until they have had the drying winds of March and the brilliant sunshine of April and May come over them.

**Genista Andreana.**—This shrub, as supplied by the trade, is pretty generally killed all over the country, at least so far as to be of no use for display this June. I raised some plants a few years ago from seed, and, as I explained last year in these columns, but a small percentage came true, i.e., yielding the partially crimson or mahogany-coloured flowers. The pan of seedlings in its entirety was planted, with the result that the common Broom (*G. scoparia*), the *Andreana*, are flourishing and flowering now in a mixed mass. Now what I want to point to especially is the fact that this crimson form got from seed is of a hardier constitution beyond all doubt. There is not a blackened twig on it, and in the same garden the worked (grafted) specimens are useless, and many quite killed. I venture to suggest that either the grafting or the *Laburnum* stock, which, I believe, is the one always employed, is not the best for scions of a variety thus proved to be otherwise more enduring.

**Arenaria Huteri.**—The pigmy herbage of this Sandwort is so dense, compact, and pubescent as to resemble that of *Androsace Wulferi*. I speak of its habit at the flowering time, and its flowers for the size of the other parts are quite large, resembling the full-sized pips of a white Lilac. It is of slow and dense growth, and during flowering the specimen is simply a flattened ball of snowy white bloom. It is quite cold and damp-proof. My plant has been two winters in the open.

**Spiræa Anthony Waterer.**—This is a decided advance on *S. Bumalda*; even the as yet small plants prove the free-flowering habit, as well as the deeper rosy crimson corymbs of blossom. I notice that in the case of every plant there is a tendency to variegation in the leaves—creamy white. One more question occurs to my mind about this *Spiræa*. Fine as it is, I do not see much difference between it and a kind I have grown two years as *Spiræa Bumalda ruberrima*. Perhaps it will be more just to compare them when the Anthony Waterer kind grows into stronger bushes.

**Sobolewska clavata.**—This, to those who have not fully proved its capabilities, may need a special note—a note of warning, so to speak, in the way of advising a not too hasty judgment upon it. It is a crucifer with round, thick clavate leaves. The flower-spikes run up in slender form quite 2 feet. At first the little white flowers may seem disappointing; they are inferior to those of the common *Arabis*, but the plant goes on and on spreading and branching. There is a wonderful development of lateral florescence and the early flowers are long-lasting; the consequence is, you get a cloud of pure flowers, elegantly posed on slender stems, which seen at a short or long distance is most effective. It is in this way only that I can see any value in this plant for decoration. I should advise that it be planted in threes or sixes, though in time the roots, which run somewhat, will make a wide specimen; but it is time that means all with this species, for if not seen in a bold piece the first year I fear many would pull it out. It certainly deserves a better fate, and judiciously placed it will do capital service.

**Edraianthus serpyllifolius.**—Never have I seen this lovely alpine flower so profusely as this spring. Plants need to be three years old before they give a true idea of what they really are, yet flowers occur the first year from cuttings and seed. Tender care must be bestowed on young stock, as a slug may spoil half-a-dozen in one night.

**Edraianthus pumiliorum.**—Charming as the above is, this to my mind is even more so, the

flowers being larger and of a sheeny red-purple. The flowers are set off by the quite distinct foliage, which is grassy, all radical, and of a grey or glaucous hue. The *Edraianthi* are supposed to be short-lived, but I think this is an error. The contrary is proved if you keep slugs away from them, but how to do it is the puzzle—they are so partial to these dainty things; and not only do they eat the tops in summer, but in mild periods in winter they will eat off the crowns right down below the surface. My plan is to dash over the plants once a week some dry silver sand; this is otherwise beneficial, as it repels the hot sunshine and helps to fix the slender collars.

**Dianthus Michael Foster.**—This is an early Pink of the alpine class. It is a sort of glorified *D. alpinus*, and suggests itself as something between *alpinus* and *neglectus*, and a better perennial than either. I have a strong specimen of this first now in full bloom, stature 7 inches.

**Saponaria ocymoides splendens.**—If you want bright rosy-red colour and plenty of it, plant this by all means; it is a glorious variety for bright weather, lasting a long time in the most exposed positions, but for effect at twilight the paler type is not to be despised; indeed in the evenings of the latter half of May and well into the month of June it actually lights up the rock garden by its myriad flowers and broad masses.

**Primula Reidi.**—This is now in bloom, and a plant to linger over. How rapidly the whole plant develops; there is scarcely a part of it to be seen in the last week of April, and by the first week in June or earlier in more salubrious climates than Yorkshire it gets into flower. The flowers are creamy white with just a suspicion of blue milk-white in the older flowers; the perfume too is as peculiar as it is full and spicy. I get seedlings to flower sometimes the first year, mostly the second, yet it is a capital perennial Primrose.

**Asperula Athoa** (Boiss.).—This is one of a group that has not long been grown here. None of our native species can scarcely give any idea of its habit and stature. It flowers profusely at a height of 2 inches to 3 inches; the whorled foliage is dense, thick and woolly, and the clusters of rosy-carmine flowers terminate every half procumbent stem. At the first glance a flowering specimen suggests an *Androsace*. I am assured of its hardiness, but hitherto I have kept it under glass in a cold frame with air always on.

**Asperula nitida** (Sib. and Sm.).—This is a totally different species; the tufts of leaves are as dense as a Club Moss, and of deep shining green, as implied by the name, and the bright coral-red flowers are in such compact clusters as to almost cover the foliar cushions; the total height when in flower is little more than 1 inch. Wedged between stones in vegetable soil that keeps moist it does well, and the effect is exquisite.

**Asperula carpathica** is a more lax plant, growing 3 inches to 4 inches high, somewhat resembling *hirta* in other respects; flower bright rose. I am sure this trio of alpine Woodruffs will delight alpine plant growers.

**Iris verna.**—I have now tried this fully exposed several years, and find it quite hardy. Stature 3 inches, or 6 inches to 7 inches when in flower. It likes a semi-boggy soil, and so grown is an evergreen plant with me. Its flowers are large for so small a plant, appearing in April, May, and June. They last but two or three days, are delicate in their colours and chaste to a degree. It is just the thing for the base of the rock garden with an east or west aspect.

**Saxifraga cotyledon.**—I believe this is less common than its variety *pyramidalis*, or even the queen of Saxifrages, *longifolia*, but it is, I think, superior to either as a flowering plant. Compared with these, usually considered the two choicest for big and symmetrical panicles of white bloom, its plumes are larger, denser, and more elegant, and the flowers being pure white (without spots) with longer and narrower petals, the effect is far more graceful. It only needs to be seen side by

side with the better-known favourites, and I think no one would dispute its superiority.

Woodville, Kirkstall.

J. WOOD.

#### SEEDLING DAFFODILS.

I AM obliged to Mr. Engleheart for advice given on this subject, and quite agree with him as to the undesirability of raising varieties that have an element of weakness in them. We want Daffodils that can be left to care for themselves in the orchard and woodland, and for this reason I selected the old double to breed from. I think by the aid of old Ajax we may in time secure a race of Daffodils, parti-coloured and white, that, whilst giving us the exquisite tint and form for instance of *cernuus* or *moschatus*, will be endowed with the vigour and reliability in all soils of Ajax. As regards the Tenby, I did not know, when some years ago I crossed it with *cernuus*, that it cannot be relied on in a general way. I am the fortunate possessor of a soil in which the Tenby flourishes like a weed and *cernuus* increases freely. I have had clumps of the latter not in any way disturbed for six years, and bearing some thirty blooms on stalks 18 inches high. I naturally thought that by making the Tenby the seed-bearer I should, perhaps, get pale-coloured varieties with a vigorous constitution. However undesirable it may be to cross two delicate kinds, there can scarcely be the same objection to the union of two varieties, one of which is capable of infusing hardiness and vigour into the offspring. Mr. Engleheart is aware of what has been done in this way with such things as *Rhododendrons* and *Gladioli*, the union of a tender and very hardy kind having given us a race of beautiful and thoroughly reliable garden flowers, and in the same manner, by using a robust variety as seed-bearer, one ought to be able to work some such change with Daffodils. Some of my seedling doubles are between Emperor and Ajax *Telamonius*. I think they will yield extra large blooms, they are so vigorous. Unfortunately, I have little time for hybridising Daffodils, but ever year I raise a few always from a different cross. The worst of it is, one has so long to wait, but the first five years bridged over, one may annually expect some new form, which, if not sufficiently distinct to be worthy of naming, will add to the attractions of the garden.

J. CORNHILL.

**Snowdrops in swamps.**—Has anyone tried the Snowdrop in swamps, flooded in winter, or other very damp or semi-sodden places? Or have any amateur readers of THE GARDEN grown them in water like *Hyacinths* or other bulbs? I have had sufficient experience in these directions to know that it can be done, but would be glad to have the experience of others. The finest show of common Snowdrops I have ever seen was in a swamp in a wood so soft and treacherous, that it was unsafe to stand five minutes in one place.—D. T. F.

**Stock Princess Alice.**—This beautiful white Stock is again proving itself most useful. Plants raised at the end of February and planted in the open borders in April have already grown to a large size, and are commencing to flower freely. Its earliness is one of its chief recommendations. Another good point about it is the freedom and strength of the side shoots and bloom spikes. With East Lothian and other strains one may get a grand central spike of bloom, but the secondary ones are of ten comparatively poor unless when the plants are grown on rich soil. With Princess Alice, however, these latter are always large and full, and the more the knife is used the more it grows and flowers. In this latter respect it certainly has no equal. All who esteem white Stocks should grow it.—J. C.

**Single Pyrethrum.**—That these are far more pleasing as cut flowers than are the double forms there can be no question, whilst their beauty in the garden is also great. But I want to ask of someone who may have experience whether the dark-coloured varieties are more en-

during when cut and placed in water than are the light-coloured ones. On an exceedingly hot day (May 30) I had given me to take home a few blooms of a dark red and of a pink form. All in the great heat soon flagged in the hand, and I slipped them into a loose umbrella. When I reached home they were placed in water. The pale ones lasted a few days, the red ones are still fine after nine days. I think the flowers were all of the same age, as the plants had been hard picked a few days previously.—D.

**Giant Poppies.**—There is a great fancy for blooms of these perennial Poppies on the part of ladies who purchase them in the market, where, having been exposed to the sun for several hours, it is found almost ere the flowers have been carried home the petals fall. These Poppies should be purchased only when in an unopened state. It is very different when the flowers are cut in the garden and set fresh into water, though even then no flowers are so enduring as are those cut early in the day and with the buds just breaking. Those who offer flowers for sale should have cool, moist places in which to keep them in hot weather. Here in the Kingston market cut flowers of all description are fully exposed to the sun and wind, there being no shelter of any description for them.—A. D.

## CHRYSANTHEMUMS.

### CHRYSANTHEMUM NOTES.

THERE should be no delay in getting the plants into the pots in which they are to flower. Early potting is a better plan than feeding with stimulants whilst the Chrysanthemums are in small pots, although the latter practice has been resorted to at times through being unable to do the potting because of other pressing work. I do not like the roots of any plant that is intended for growing into a large specimen to become woven and interwoven whilst the same is in a small state. There will certainly be a severe check when such are transferred to other pots, but if a plant be shifted just when the roots have taken to the earth by reaching the sides of the pots and just running through the drainage hole, we reduce the check to a minimum. Chrysanthemums like a loamy soil, and I generally try to provide that of the best quality. Loam, of course, varies according to the locality where it is cut; that of a yellow colour is most liked, and highly valued if full of fibre. Use two-thirds of loam in the compost, the other third being made up with horse manure, gritty material and bone-meal. The above is a good, sound, wholesome soil, which is preferred to a mixture made up of all kinds of fanciful things. The potting should be done in a very firm manner. This item cannot be too often mentioned. Stand the pots well apart in their summer quarters, which should be the most open spot in the garden. Neatly stake each plant so that the growth is secure against wind. For a week or so after the repotting has taken place it is advisable to water at the roots very sparingly, and if the weather be hot and dry at the time, a sprinkling with water overhead twice a day will prevent the leaves flagging. As I write there are indications of a sunny season. At least we have had during May above the average of sunshine, which fact makes one hope such weather may continue. Sunshine is most suitable for Chrysanthemums and a dry season, one that brings out the better qualities of the blossoms. Being a moisture-loving plant, the work of watering is considerable throughout dry summers, but such work must be cheerfully done and will bring its reward in the autumn.

The behaviour of varieties in certain seasons is an interesting study. For example, the dull,

sunless summer of last year was unsuitable for the development of choice blooms of the variety Lord Brooke, so telling in its colour of bronze. Scarcely a flower was to be seen of the terracotta-coloured Col. W. B. Smith. The rich dark crimson Wm. Seward was conspicuously absent, and the equally rich crimson Edwin Molyneux not seen in anything like good form. White-coloured varieties seem less affected by seasons than other shades, unless it be yellows, which are always good. The gigantic thick-petalled variety Mrs. C. Wheeler was not at all good last year, and consequently rarely seen at shows. Personally, this type is not one that commends itself, for not only is it coarse, but requires the purest of country air as well as the best of management to obtain exhibition blooms, and cultivated for other uses, that is, when allowed to grow a large number of flowers to a plant, Mrs. C. Wheeler assumes the form of a scanty arrangement of a few large petals with a huge yellow centre devoid of grace or colour. Beauty of Castlewood is very little better, and if one were to discontinue the growth of such varieties there would be very little loss. An interesting article on page 362 of THE GARDEN deals well with the subject of coarse varieties of Chrysanthemums. The remarks of Mr. J. C. Tallack are excellent, and I think with him that a system which assists in perpetuating such coarse, ungainly Chrysanthemum flowers as International, Mrs. C. Harman-Payne, Etoile de Lyon, Duke of York, Mrs. E. W. Clarke, Miss Ethel Addison, and others is wrong somewhere. It occurs to me that "the best judges" might exhibit a little less disposition to lengthen the number of "points" each bloom must possess, and a trifle more boldness when judging. That is to say, they might deal with coarse blossoms in a similar manner to that which obtains among our Rose-loving friends. An overgrown flower is marked a bad one, and as such tells, of course, against the exhibitor. But by this means Paul Neron, Ulrich Brunner, and Cabbage-like specimens of Her Majesty are duly apportioned their proper weight, and the prizes given to more charming, if less bulky, specimens. If judges of Chrysanthemums set the example exhibitors would soon follow, but at present the latter know that "weight" is the principal aim. Apparently we cannot hope for a more desirable taste in the matter of types of the Japanese Chrysanthemum being fostered by the National Chrysanthemum Society through its floral committee. Size seems to be the one thing needful. On referring to their meeting of October 24 last, I find their highest award was given in each case to Mr. R. Ballantine, Mrs. H. J. Jones, Reine d'Angleterre, and Amiral Avellan—varieties which my notes of the time tell me are absolutely devoid of graceful formation, if we except perhaps the first named. That possessed a dingy rose-lilac tint, but certainly had long flowering florets. The charming deep rich yellow Pallanza, the exceedingly bright bronzy M. C. Molin, the well-formed distinctly tinted M. Aug. de Lacviver, not being giants in dimensions, received the commendation of that body. I venture to say, however, that with or without the latter honour the last named sorts will become more popular than those first named. Regarding the best varieties of the autumn flower, I personally should like to return to the time when Mlle. Lacroix was thought the highest type of beauty. I do not mean the time in its literal sense, for the wealth of varieties was so limited then to what it is now. We have at the present time most handsome kinds of almost every hue of colour.

Mlle. Thérèse Rey, Sunflower, Wm. Seward, the new variety Duchess of York are splendid types of colour and form. Col. W. B. Smith and Lord Brooke, of loose incurved form, are fine examples of showy beauty. Varieties as these require no definition; their merits appeal to every eye.

With me insect pests are less numerous than usual. Green-fly is fairly persistent among the tender points of the stems, but this is easily killed by dusting with tobacco powder. If through neglect we allow our plants to become thickly infested with this or any other pest, damage to good health will accrue. The leaf-mining grub has not yet been found at all, but there is time for it. As late as July I have known it troublesome. Hand-picking is the only remedy I have tried; this is effective. If earwigs are caught now we considerably lessen the likelihood of attacks when our plants are in bud later in the year.

The disposition of the variety Vivian Morel and its sport Charles Davis to develop flower buds early in the year is most marked this season in every case where I have seen the sorts. I fear this habit has become constitutional, and may in time considerably affect the high position obtained by both as exhibition flowers, for we must cut the plants back and by so doing give them a serious check. Fortunately these varieties are very quick growers and in a short time push out other shoots, which will eventually produce handsome blossoms. Late-struck plants are the least affected, and this mode of culture is commended. In any case the mode of procedure is to cut away the portion of the stem which has produced the shoots with buds—this will be about 6 inches in length—to hasten the growth of other shoots.

H. SHOESMITH.

## GARDEN FLORA.

### PLATE 1018

#### CONE-FLOWERS.

(WITH A COLOURED PLATE OF RUDBECKIA MAXIMA AND R. PINNATA.)\*

A FEW years ago the Cone-flowers were all comfortably and contentedly included in one genus, Rudbeckia, but in the new Kew Index we find them again separated into three or four, and the two flowers so gracefully combined in the accompanying coloured portrait are of different genera, the larger being Rudbeckia, and the smaller Lepachys. Must gardeners submit or rebel? It is trying to their patience to find "Genera Plantarum" and Nicholson's "Dictionary of Gardening" so soon superseded, and we will venture here to continue the name Rudbeckia for all the Cone-flowers. These North American composites make fine showy plants for the hardy border, flowering in late summer and autumn. The purple kinds (now again called Echinacea) have, I think, been already figured, and have certainly often been described in THE GARDEN, so I shall mention about eight yellow kinds, confining myself to those with which I am familiar in my garden at Edge. To begin with the portraits:—

R. MAXIMA is a fine, handsome plant growing 6 or 7 feet high, having flowers densely set with broad golden rays and produced in August and September. The large glaucous oval and entire leaf at once distinguishes it from others of the

genus. Being a native of the warmer States of America, it thrives best in warm gardens and in hot summers. I raised many plants of it ten years ago from American seed, and in 1887 and 1893 it was grand, but cold, wet summers, more than the frosts of winter, have greatly reduced the dimensions of the plants, which want renewing from imported seeds.

RUDBECKIA (now Lepachys) PINNATA, the other flower in the portrait, wants no description, as both leaf and flower are so well represented. It grows 4 feet or 5 feet high, flowering from July until hard frosts overpower it. It is not a long-lived plant, getting too hard and woody at the base to continue to break well, so it is better to keep a few seedlings on hand. Seed is abundantly produced and easily raised. Plants flower in the second year, and continue about five years more.

R. CALIFORNICA is the giant of the tribe for size of flower and cone, the flower being often about 6 inches across, and the cone 2 inches high; leaves, flower-stalks, and root are equally robust. The flowers come early in July; they have few and horizontal rays, and are solitary on the stalks, their size making up for their small number, and the whole plant having a majestic appearance. It is better for frequent division, exhausting the soil if left to itself for several years.

R. LACINIATA is the tallest of the Cone-flowers, though not so stout a plant as the last. I have one in a moist, sheltered corner which Mr. Robinson, when visiting my garden a few years ago, said was the handsomest plant I had. It is still flourishing, and grows every year about 10 feet high, though 6 feet or 7 feet is the ordinary height of the type. The leaves, as the name implies, are unevenly divided into narrow ribbons, or cut into larger lobes, different individuals varying much in leafage. The flower is large, the rays curved downwards so as nearly to touch the stalk, and the cone is greenish. Plants live many years without spreading much, but are easily divided, and self-sown seedlings come up round if the seed escapes the green linnets and chaffinches, which delight to eat it.

R. LEVIGATA (nitida?).—About ten years ago a very tall and late Cone-flower was sent to me from St. John's Nursery, Worcester, with the name R. levigata (Pursh.). The sender told me that he had both plant and name on good authority from America. The general habit is that of R. laciniata, but the leaves are less incised than in any of that species; the flowers, though smaller in outline, are more regular and plentiful, and have broader and more golden rays. They begin to open when R. laciniata is over, and continue into November. From a gardener's point of view the two plants are quite distinct. Twice I sent specimens to Kew Herbarium for a name, and twice it was returned as R. laciniata. I also sent living plants to Chiswick, when the Aster conference was held, and to Kew Gardens, but the name R. levigata was not recognised. Asa Gray gives R. levigata (Pursh.) as a variety of R. laciniata. I have lately seen this plant described as R. nitida, but I do not find it agree with Asa Gray's characters of that species. Whatever it is, it is worth growing as a late autumn flower. We must remember that many of these North American composites readily form hybrids in gardens, and this may be one.

R. SUBTOMENTOSA is another distinct species. The flowers show hardly any raised cone; the disc is very black, and the golden rays, about an inch long, continue horizontal, so that it would hardly be taken for a Cone-flower. It grows 4 feet high, flowering late and very freely, and is easily increased by division. Young plants succeed best; when old they are apt, like R. pinnata, to get so hard at the base that large limbs suddenly lose their vital union with the root and wither before flowering.

Two remain to be described, of which the flowers are rather similar, but the habit very different. They are—

R. SPECIOSA, to which gardeners give the unauthorised name of R. Newmanni, though I never could discover why. It is so well known, that I

\* Drawn for THE GARDEN by Miss E. F. Sneyd in the garden of the Rev. C. Wolley-Dod. Lithographed and printed by Guillaume Severeys.

need say little more than advise those who wish it to succeed in hot and dry summers to dress the surface with rich compost and to water it well, or it withers prematurely.

R. HIRTA is said by Asa Gray to be "annual or biennial." It certainly requires frequent renewal from seed. It flowers generally more than once, not often more than twice, but its life is of uncertain duration. It grows generally about 18 inches high and produces a large spreading panicle, each flower being often 4 inches across. Two-year-old plants begin to flower early in June, and continue gay through summer. It is well to select the largest and most golden flowers for seed. This species always attracts notice in my garden from the bright colour of the rays and the good contrast of the black cone. Similar treatment to that given to Canterbury Bells will secure a succession of plants.

Excepting R. maxima, I have, in a long gardening experience, found no difficulty in maintaining a stock of all these Cone-flowers. R. pinnata, R. laciniata, R. hirta ripen plenty of seed every year. I never found ripe seed on any of the others, but they are all easily divided; the whole tribe likes a rich moist soil and a warm aspect. C. WOLLEY-DOD.

Edge Hall, Malpas.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**TOMATOES.**—The dreaded disease has already appeared in several gardens in this neighbourhood, especially where it has long been the custom to sow home-saved seed. This leads me to think that, as with many other plants and vegetables, so with Tomatoes, a change of seed is very necessary. To guard against the malady a comparatively dry atmosphere must be maintained and above all the syringe never used over the foliage. If growth is fairly strong and fruit sufficiently abundant, let well alone, as too rich top-dressings and liberal feedings are apt also to encourage the disease. Where Tomatoes occupy a house to themselves their special needs can be readily attended to, and I would recommend that afternoon damping down and early closing be not practised. There are few fruiting subjects less affected by insect pests than the Tomato; therefore a somewhat arid atmosphere continually is beneficial rather than otherwise, provided always plenty of root moisture is supplied. Sometimes whole batches of plants are ruined by attacks of wireworm, the same having been in the soil when the plants were potted. The first sign of their presence is a yellowness in the foliage, together with slight flagging during sunshine; this is caused by the worms boring their way up the main stem. The best remedy is to procure some quite fresh horse droppings and spread them thickly over the surface soil of the pots; the smell of these after being watered will entice them down from the stems, when they may be destroyed. The manure should be examined every second morning until a more healthy growth is resumed. I had a batch of plants so affected last year owing to newly-cut loam being used in potting, and the above trap answered well, the plants afterwards growing and fruiting well. Prevention being better than cure, it is always more practicable to use soil at least two years old, as then these pests are more likely to have grown to a discernible size and may be picked out and destroyed. Tomatoes for successional work may still be sown, using single small pots, this being not only better for the plants, but a saving of labour in the end. Place the pots in a moderately warm house until the seed has germinated, then remove immediately to a greenhouse temperature, as coddling at this advanced date when pipe-heated structures run up so high is ruinous.

**ASPARAGUS.**—Where seed for the supply of stock plants was sown in March, as advised, thin-

ning out will now be necessary. This should be done with a free hand, as if left too thickly, much difficulty and damage will follow when the plants are lifted for transplanting. A mulch of rotten manure between the rows will do much towards preserving moisture about the roots, which at present lie very near the surface. Give several good soakings of liquid manure during the growing season. Where beds exist for forcing, growth will now be very far advanced, and the most must be made of the time for feeding the roots to strengthen the crowns for next year's work. Keep down weeds either by hand-weeding or by the application of a little salt twice in the summer, the latter plan, of course, being by far the most economical, salt also helping to keep light porous soils in a moist condition. Nitrate of soda is one of the best manures for Asparagus, if used carefully in showery weather or watered home by watering cans. All Asparagus beds are the better for occasional floodings of farmyard liquid manure at intervals of a month, except where the soil is unusually retentive and in wet seasons.

**SELF-PROTECTING BROCCOLI.**—As a late autumn and early winter Broccoli to succeed Autumn Giant and the later sowings of Walcheren Cauliflowers, no variety can equal Veitch's Self-protecting. The sooner the first batch of seedlings is got out the better, the smaller ones, if a secondary sowing has not been made, being pricked out into a bed and well nourished for three weeks longer for successional work. The Self-protecting, being a very strong grower, needs plenty of room with a rich soil, and as, unlike the ordinary winter and spring Broccoli, which are far more hardy, it will have to be lifted and placed under cover at the approach of sharp frost, a strong sappy growth is no detriment, but rather the reverse. Some growers place the young plants in trenches, and doubtless this is one way of securing the largest heads with, in the end, the least trouble, as once the soil in these gets well soaked, it is an easy matter by an occasional watering to keep it so. Allow abundance of room between each plant, and water the trenches the day previous to planting. See also that the seed-bed is well moistened at the same time, or many of the best fibrous rootlets will snap off in drawing. Examine the centres, as this variety, and, indeed, all Broccoli, will sometimes have a percentage of blind plants. If very hot at the time it will be well to shade the plants for a week with evergreen boughs.

**MAIN CROP CELERY.**—By the time this calendar appears the main batch of Celery will in most places be sufficiently forward for putting into the trenches. Should the weather continue hot and dry, extra care will be needed in transplanting. Newly-formed trenches must be well trodden and then soaked with water a day or two before wanted, and the plants, whether in boxes, frames, or open sheltered nooks, well soaked as well. If taken up, even in a semi-dry state, much of the root soil will fall off, and the plants consequently flag and suffer. Planting completed, water home and afford shade from hot sun. Remove any suckers which may be clustering around the base of the plants and watch for the Celery maggot, which will sometimes appear soon after the young plants are put out into the trenches.

**EARLY COLEWORTS.**—Some people like to have a small batch of this most useful vegetable in early autumn, and in such cases seed should now be sown, the sowing for the principal winter batch being deferred till the second week in July. A sowing of the hardy green variety may be made at the end of July for supplying small heads in spring. Coleworts being very compact in habit may be planted pretty closely together, and if any quarter has been cleared of Potatoes or Peas, the Coleworts may be planted without any further preparation of the ground.

**RADISHES.**—These should now be sown more frequently, as when once the bulbs arrive at their full size they soon become hot and tough. The small Olive-shaped and Turnip varieties are by far the best for this time of year, the position

most suitable being a semi-shaded one and the root-run rich and moist. Strong manure is not advisable, as it is apt to give the Radishes an objectionable flavour, old Mushroom manure being best. Daily waterings are also necessary after the young seedlings come through the ground, dryness being fatal to them. The best way is to sow a small patch once a fortnight, and if the seed is sown thinly the labour of after-thinning is avoided, and birds at this season are usually less troublesome amongst Radishes and small seeds generally.

**ENDIVE.**—Where this is required for a change from Lettuce in early autumn, a little seed may now be sown on a cool moist border. A large number of plants should not be transplanted, as sometimes these extra early lots of Endive will bolt wholesale. The green and moss-curl varieties are by far the best for sowing now, leaving the broad-leaved till the July sowing. Where time and labour are scarce the plants may be thinned out to the proper distances in the seed-bed when quite small, and allowed to stand there.

J. CRAWFORD.

### FRUIT HOUSES.

**EARLY VINES.**—To keep the fruit in the best possible condition early or hard forced Vines must have more air and less fire heat, the amount of the latter being governed by the external conditions. It is important to retain the foliage in a healthy state, and during very hot weather with Vines close to the glass it will be necessary to shade in order to retain the foliage till it has performed its functions. In cutting ripe fruit it is well to clear any rods which may have been infested with insect pests, and then give them daily syringings in the evenings so as to get rid of any insect life which may have escaped. During hot dry weather the houses containing ripe Grapes should have the floors and walls damped twice daily; this will keep the foliage healthy and prevent shrivelling of the berries. Black Hamburg Grapes fully ripe will be best given a light shade during the hottest parts of the day, but Muscats require full exposure if the foliage is healthy. Vigorous canes will make a lot of lateral growth, so go over the Vines frequently, as much harm follows excessive thinning, but little and often is the best policy, as this prevents scalding and the Vines do not miss the growth. In thinning surplus growth allow the terminal shoots more play if there is space for these to extend, as root action is encouraged. In light soil more water may be required, but must be given with care, as the thin-skinned varieties like Foster's Seedling and Madresfield Court crack badly. It is best to thoroughly water these at the colouring period, mulching afterwards and thus retain the moisture. If watering is necessary it should be done early in the day, plenty of air given, and a freer lateral growth allowed for a short time afterwards. Many early Vines are much injured by being kept too dry at the roots at this season, as though forcing is at an end the roots are still active.

**SUCCESSION HOUSES.**—These will now be changing colour and at a critical point, as the Vines will require more fire heat with dull or wet weather; more air must be given also and a drier atmosphere maintained, though damping down most days will be necessary, in all cases the external conditions being the chief guide. Perfect berries, and as large as possible, can only be obtained when there is no check given, and it is the safest plan to admit a good circulation of air, at the same time giving warmth in the pipes. As soon as colouring begins leave air on the ventilators all night. A little on the front ventilators will greatly assist the colouring, and a chink on the back ventilators late in the evening will prevent sweating or moisture on the berries early in the day. The temperature for houses at this stage should now be 75° to 80° by day, the house being closed in good time and the thermometer running up to 90° or 95° for Muscats, giving 75° at night and 5° less in mixed houses. If air is given at night there will be less fear of scorching

early in the day. In all cases admit air early and in small quantities at a time. This creates a genial atmosphere; whereas high temperatures and sudden rushes of cold air cause mischief, disease, and favour insect pests. Watering at this point is important, and must be given liberally in shallow borders, doing the work just as the berries show colour. It is best to give tepid water, and if the surface is at all hard pierce it lightly with a wide-pronged fork. Give liquid manure at this stage, or, failing this, a surface-dressing of a good fertiliser, such as Thompson's Vine manure, washing it down to the roots. A good mulch should then be given, and another watering in a few days, which will keep the mulch moist and the roots moving freely to support the fruit to the finish, as Grapes never colour well when dry at the roots or in a dry atmosphere. Allow lateral growth of Muscats more freedom, stopping gross shoots, but allowing weaker ones to grow on, and feed freely with liquid manure. Early ripening of this choice Grape should be the first consideration, as it keeps better.

**LATE VINES**, such as Lady Downe's and others, will now be set or setting, and in many houses ready to thin. In thinning late kinds it must be remembered they have to hang a long time, and unless well thinned they cannot keep well. Large-berried kinds, such as Gros Colman, require several thinnings, and at least three thinnings should be given large bunches required to keep sound into the new year. Mrs. Pince, Alnwick Seedling, Alicante, and Lady Downe's all set such a profusion of small, stoneless berries that much care is required to remove these to allow those swelling room to develop. Watering and feeding the roots should follow thinning. Outside borders will be drier than usual with the little rainfall we have had through the spring months, and such borders will now take liquid manure and other food freely. The temperature in this house should not fluctuate much. Avoid cold winds, and in wet weather keep up a genial warmth in the pipes, with air on the ventilators to prevent scalding and rust.

**POT VINES**.—The roots of those for early forcing having reached the sides of the pots, they may now be fed freely, and the lateral growth stopped at the first joint from the cane: these later on can be cut quite close to the cane, but by allowing them to remain at present, the buds at the base swell more freely and the canes are strengthened. Mulching canes well advanced will save watering and promote strong growth, and there should be no lack of atmospheric moisture, with the house closed early and the canes well syringed. Small plants struck late should now be given a shift into 6-inch pots: these will make good material for another season if kept growing in a brisk heat.

**PLANTING VINES**.—It is not too late to plant young Vines struck for this purpose if the house is in condition for the plants. I have often taken a crop in May and in early June planted new canes. Those who have Vines in a bad state may with advantage plant now and grow on freely. Small houses may often be utilised for a crop of Grapes. Those planted in small borders may be fruited the following season, and they force much better than pot Vines. They may not be quite so early, but they carry a better crop. In planting spread out the roots freely—plant firmly—shading for a short time and close early, keeping close for a short time, and grow in a brisk heat with plenty of moisture, stopping all lateral growths at the first joint. Should the plants make a weak start, stop the leader at a few feet from the base and train up another leader; this will give increased strength. As regards the final length of canes much depends upon the size of the house—8 feet to 10 feet is a fair length, and the former will carry half-a-dozen nice bunches.

**VINE PESTS**.—Red spider is the most common pest among Vines, but is soon got rid of by using sulphur, either by sponging or coating the pipes with sulphur. The first named is safest and a sure cure if the leaves are lightly sponged when the pest first appears. If the pipes are covered the crop should be well advanced, but a moist

atmosphere will do much towards keeping the foliage clean. The pest usually makes headway whilst the fruit is hanging in a ripe state, so that it is necessary to keep the foliage clean up to that period. Thrips also make their appearance at this season, and in addition to spoiling the foliage, mark the berries also if not soon cleansed. Sponging with a little soft soap and tobacco water is the best preventive, and in badly affected cases fumigating is necessary, but this is risky unless done carefully by several light fumigations in succession. Mildew is the worst Vine disease, and must have speedy attention when it appears. Vines with fruit well advanced are more difficult to deal with in these cases. Sponging all affected leaves with soft soap and sulphur mixed, or Bentley's mildew specific will get rid of the pest in its early stages, but this is not sufficient. The pipes should be painted over with thick sulphur solution and the house kept drier for a time. In mixing add a little oil to the sulphur, causing it to adhere to the pipes. After resorting to the above air carefully for a time to keep up a brisk temperature, and the pest will not spread. Should the bunches be infested cover lightly with dry sulphur: this may be washed off after a time and will not affect the berries if carefully syringed. Mealy bug may be troublesome, but this can be got rid of by persistent efforts. When the Vines are at rest is the best time to war against this enemy, but if present now, by going over the canes twice a week with a soft brush dipped in methylated spirit the pest may be kept down.

G. WYTHES.

## KITCHEN GARDEN.

### LEEKS.

IN seasons of plenty the above vegetable is often despised, but in such winters as we have recently experienced the Leek is most valuable, being more hardy than most vegetables, and after a protracted frost mild in flavour. Although Leeks are not so popular in the south as in the north, I feel sure they will have been a welcome addition to the supply this spring in gardens where hitherto there was little demand for them. They are deserving of extended culture, as they are most wholesome and form a really tasty dish when well served. In a note on the value of this really useful vegetable I do not intend to go at length into the details of culture for exhibition, but to treat of ordinary culture for home use and to name a select few.

Of late years we have had several additions to the list of kinds, some noted for their length, others for their thickness. Length may be an important point for exhibiting, but for ordinary use I prefer those thick at the base and uniform in size, as when prepared for cooking there is less waste. For mere flavouring, the green tops are all that is required, and for this purpose the plants are grown thickly. Those who require exhibition plants raise them early in the year, sowing the seed in heat; but as the plant is very hardy, by sowing in mild weather at the end of February or early in March on a warm border, covering the bed with mats in frosty weather, roots may be had for winter use quite large enough if well fed during the growing season. Now is the time that the earliest lot of plants should receive attention. The best mode of growth is in deep drills on heavy land and in trenches on light land, much the same culture being required as for Celery. In growing exhibition Leeks, the plants are usually pricked out into boxes and ready for their permanent quarters by the middle of May, but as I am dealing with them as an ordinary crop, I will only touch upon the necessary culture. Plants sown in the open

should always have plenty of space to develop, as sturdy plants with ample roots do not receive a check like weak, crowded ones. They delight in good solid manure dug into the trenches, with ample supplies of moisture and liquid manure as growth increases. In planting, the roots should not be twisted or bent in any way, but placed quite straight and made firm in planting.

I advise trenches on light land for various reasons, the chief being, moisture and food can be more readily given to the plants, and moulding or blanching is less difficult. Excellent results may be obtained by growing on the surface if due attention is paid to manuring and watering, with abundant food during growth, but even then it is advisable to plant in shallow drills drawn 2 feet apart. The plants, if a large kind or planted early, should be 10 inches to 12 inches apart. Many do not mould up in the old-fashioned way with soil, but bandage the stems; others use drain pipes and fill in with cocoa fibre or fine soil, but for ordinary use moulding up with soil will suffice. It is advisable to make two or three plantings where this vegetable is liked, the last on a cool border, as the produce will last well into June the following year if lifted in May and placed in a shady, moist border well manured. For early lifting I prefer the Lyon types, whilst other good sorts are Dobbie's Champion and Ayton Castle, all three being specially adapted for exhibition, early winter use, and noted for their mild flavour. For late use the older Musselburgh is difficult to beat, and, to show its hardy character, we have it quite sound and good at this date. It is large, of good flavour, the last to run to seed, not so thick at the base as the Lyon, but superior for late use. There are other varieties, but I consider the above selection the best for use from November till June, and, if given good culture from the start, few vegetables will give a better return.

G. WYTHES.

**Bolting in Cabbages**.—In THE GARDEN of May 25, p. 363, "J. C.," Newark, writing on Cabbages bolting, praises Ellam's as an early Cabbage on account of its freedom from bolting. Whether it is the variety or the mode of culture I am not prepared to say, although I believe too early sowing of the seed is often the cause; but whereas in other gardens bolting is more or less strongly in evidence year after year it is almost unknown with us, and I depend almost entirely upon Ellam's for winter planting. It is large enough for most purposes, is good in quality, comes early, and by planting 18 inches each way, nearly as large a weight can be taken off a given piece of ground as by planting larger growing sorts. This year I am trying Sutton's Favourite, with which I am much pleased. It is solid, compact, very early, and not one of the plants have bolted. Although we have many varieties of Cabbage already, I think this variety will be largely planted as soon as its merits become known.—WM. HARRIS, *Uproot*.

**Pea Gradus**.—As a good early Pea I can strongly recommend Gradus. For some years past I have always sown Duke of Albany in pots, planting out when ready; but Gradus is much earlier and dwarfer, with large pods of a very distinct Marrow type. It may be asked, why sow Marrow Peas at the end of the year when better results are secured from the smaller varieties of the Chelsea Gem section? But such varieties as the Duke or Gradus soon fill the basket, are more appreciated in the kitchen, and as they are only a few days behind the smaller kinds, give a better return for the same culture. On heavy clay soils it may not be advisable to sow large Marrow Peas at the end of the year, nor do I advise sowing in any soils at that date in the open ground, as good results cannot be expected in our fickle climate. My plan is pot culture, and those

who grow in pots to plant out early in spring well know how admirably such Peas succeed if not forced too hard and attended to when planted. The fine plants at the Temple show proved how well Peas force, but there must be ample time allowed. I find when Peas are sown in good-sized pots and brought on very slowly there is less check at planting and they soon go away grandly. Gradus is a 3-foot Pea, with a large, full pod and of splendid flavour. To show its earliness, I have this season plants podding freely from seed sown in the open the end of March. It is certainly the earliest of the large Marrow type I have grown, and when planted out of pots at the end of March in an average season, a crop may be assured within two months from time of planting. I have named Duke of Albany as good when forced, but Gradus is a decided improvement in height of haulm, earliness and free cropping; indeed, in this latter respect it is superior, as though the Duke crops freely, it comes in all at once; whereas the newer variety is equally free and lasts longer in bearing.—G. WYTHES.

**Early Potatoes.**—An early Potato should combine earliness with productiveness and good quality, and in my experience, after a fairly numerous trial of sorts over a number of years, there is nothing better to be had than the three following sorts, viz.: Ringleader, Early Regent, and Puritan. They come in fit for use in the order named, and invariably yield a heavy crop of good even tubers of first-rate quality. We do not want to grow a number of varieties, but a few reliable sorts in quantity. In the above trio the gardener who has a large family to provide for has three Potatoes of undoubted merit, which will prove alike satisfactory both to himself and his employer.—W. M. HARRIS, *Upcott*.

**Mulching and watering Asparagus beds.**—With protracted drought the Asparagus crop on light soils or in raised beds will be light, but it may be greatly assisted by mulching and watering afterwards. Spent Mushroom manure is of great value as a mulch for this crop in such seasons, and if well watered once a week after mulching there will be better and more succulent grass. I would also advise dressing with fish manure before applying the mulch, as it is a grand fertiliser; or, failing this, use salt freely and water it in, as this will keep the surface free of weeds, in addition to supplying nutriment. New plantations should likewise get attention. If on the flat, with a wide space between the rows, it is an easy matter to place litter close over the roots, or if in beds, to cover the beds. This will greatly assist root action and prevent dryness, and one thorough watering will tide the plants over a long time. Asparagus is not nearly as good in flavour when grown on a dry hot soil, and is much smaller in size than when assisted by mulching and watering.—S. M.

#### SOWING WINTER ONIONS.

LAST autumn I intimated my intention of sowing a portion of my Tripoli Onions on a plot occupied for two years previously by Strawberries, a friend having told me that very fine Onions that had thin necks and kept well were annually grown on a similar plot in one garden in this county. The seed was sown the second week in August, the variety being Sutton's Leviathan, and the surface of the old Strawberry bed was so hard, that it was with difficulty the drills were drawn out. The seed germinated rapidly, and as soon as the young Onions would bear handling their numbers were reduced, the final thinning being left, of course, until spring. Another plot was prepared in the ordinary manner, with plenty of manure, and seed of the same variety sown on the same date. After the Onions had grown to a good size in October we had several gales of wind, the result being that many of the plants on the prepared plot of ground were much loosened at the base; whereas all those on the firm ground remained unmoved. I thought this an advantage at the time, as my

experience is that once autumn-sown Onions become loosened through wind at the bottom, frost, should it prove severe, is certain to play havoc with them. It may interest some to know that not one blank occurred through the frost in the row sown on the old Strawberry bed, and that at the present time these are much more shapely and larger bulbs than those on the other part, while only one or two thick necks are to be seen. In reply to some remarks on this subject last autumn, the editor stated that in one garden in Scotland where spring Onions had always failed an old Strawberry plot was heavily mulched in autumn with rich manure, the strength of which was washed in by the winter rains. This was raked off in spring, and without any further preparation the drills drawn and the seed sown, with the result that Onions of the finest size and quality were produced. Some years ago old gardeners used to grow many of their spring Onions on slightly raised beds, having a narrow alley between, and if by chance a seedling came up in the hard alley and was allowed to grow, it always made a larger bulb and had a better neck than the majority of those on the beds. These combined facts prove, I think, that Onions enjoy and, indeed, require a firmer surface and root-run than can be secured by any treading or even rolling. Certainly those who have much difficulty in growing this important crop might, if practicable, give the old Strawberry bed system a trial. If winter Onions are to be sown and the surface cannot therefore be mulched with manure, then feed liberally with liquid manure when in full growth.

J. CRAWFORD.

**Turnip Orange Jelly.**—I do not think the merits of this Turnip are as universally known as they should be. For July, August and September use it has few equals, standing drought well and seldom running away to seed. Moreover, where a yellow-fleshed variety is not objected to, its flavour will be found irreproachable. Where Turnips are wanted for exhibition during the above named months, Orange Jelly is a capital sort to grow, as so many of the white section are liable to develop foul tap roots during hot weather and to become infested with the Turnip grub, which entirely spoils them for the purpose. Although I look upon the old Chirk Castle as the best all-round winter Turnip, yet Orange Jelly is a fitting companion, and gives a pleasing change on the dining table. Like all other Turnips, it needs a cool moist border and liberal thinning.—J. C.

**Winter Spinach.**—Although of course the seed will not be sown till August and September, the present is a very good time to take the preparation of the plot intended for this important crop in hand. In soils infested with wireworm, a good quantity of gas-lime may well be dugged in, and afterwards a little more, to which may be added burnt garden refuse, wood ashes and a little root, sculled in immediately beneath the surface. There will then be sufficient time between now and sowing to allow of the strength of the uppermost dose to wash down to that which was dugged in. In ground so prepared the pest seldom attacks Spinach roots, and the above ingredients, having by sowing time lost much of their strength, act as a good fertiliser to the crop. Ground on which early Cauliflowers have been grown will do well, it being necessary to clear off the old stems as soon as the crop is cut, as leaving them in the ground after this only tends to impoverish it.

**Cauliflowers.**—I do not think that we shall easily beat the Early London Cauliflower for sowing in the autumn and for cutting before Peas come in. For use in private establishments varieties of the Snowball type may be good, but they are of little use for market, being generally too small. Early London is at least a fortnight earlier than Walcheren if sown at the same date, and this makes all the difference in prices, as the market value of Cauliflowers drops considerably as soon as Peas can be obtained. We have been cutting this variety from autumn-sown plants for

the past ten days, commencing on May 24, and Walcheren is only just ready. I do not wish to say a word against the latter variety, as it is one of the very best kinds of which to make successive sowings; but where earliness combined with good size is required, Early London must be grown. The Pearl has often been praised in your pages, and to come in succession to early varieties nothing can be better. If this is a selected stock from Walcheren—as it is generally supposed to be—it is very distinct and true, being dwarf and compact, the heads of good shape and colour. I have never met with much success from autumn sowings of the Autumn Giant type, and though this has been recommended I cannot think it advisable in gardens where the soil is light. These big Cauliflowers appear to me to want the cooler days and nights of autumn to bring them to perfection, and I can see no necessity for growing them for early work.—J. C. TALLACK.

**Tomato Duke of York.**—At the Southampton show held on Whit Monday, Mr. T. Hall, gardener to Sir S. Montagu, Bart., M.P., exhibited in his first prize collection of vegetables a dish of handsome fruit of this Tomato. They were not large, but perfect in shape and of really good colour. Such fruits as these are preferable in every respect to the large corrugated, rough samples too often met with.—E. M.

**Prickly Spinach in summer.**—Mr. Young's experience with the prickly Spinach sown in summer will be of service to those who find a difficulty in growing this vegetable during hot weather and on certain soils. His note also reminds me of the fact that the summer Spinach is equally good for sowing in autumn for a winter supply; in fact, a bed of it did me more service by far last spring than did the ordinary winter variety, it standing the frost better and producing larger and better leaves. A friend of mine told me it was his practice always to sow the summer variety in autumn. This rule holds good with other subjects, notably with Spanish or so-called spring Onions.—J. CRAWFORD.

#### MAY IN SOUTH DEVON.

THE temperature for the last month has been decidedly high, the mean average being 54.5° against 51.8°, which is the average for the last sixteen years. In May, 1894, the temperature was 50.9°. The thermometer on the grass has not once fallen to freezing point, the nearest approach being on the 2nd, when 35° was registered.

Rainfall amounted to 0.66 of an inch, the average for May being 2.29 inches, and the rainfall during May, 1894, 2.43 in. The total amount of the rainfall since January 1 is 10.31 inches, against 12.65 inches for the corresponding period of 1894.

The amount of sunshine registered was 298 hours 35 minutes, against an average for May of 219 hours 35 minutes, and a record of 203 hours 50 minutes last year, the total amount registered for the five months of 1895 being 790 hours 15 minutes against 706 hours 25 minutes for the same months in 1894. As regards wind, May has been a quiet month, quieter than any of the preceding thirteen. The total horizontal movement was 4637 miles and the greatest hourly velocity was attained on the 15th, when a rate of 31 miles per hour was recorded. It is curious to note that, although with a lessened rainfall of 1.77 inches compared with May, 1894, the mean humidity of the past month has been greater, that of May, 1894, being registered as 72 per cent. and that of May, 1895, as 73 per cent.

The flower garden in May is not entirely bereft of Narcissi, poetical recurvus and plenus lingering, till the June days begin, in shady spots where the Virginian Cowslip (*Mertensia virginica*) hangs its drooping heads of turquoise blue. In the Lily bed, where a dozen varieties are making good growth, only one, *L. pyrenaicum*, is yet in bloom, a pretty Lily with its chrome-yellow Turk's-cap and red anthers, but not one to be used for indoor decoration on account of its unpleasant scent. A clump of the Wood Lily (*Trillium grandiflorum*)

has been a beautiful sight. The flowers become more numerous and larger with each succeeding year, and the chaste loveliness of their snowy petals standing out from the green setting of the wide leaves should commend them to all flower-lovers. Peat or leaf-mould should enter largely into the composition of the soil in which they are planted, and a situation in the partial shade should be given them. In the herbaceous border *Doronicum plantagineum excelsum* in masses has been a fine sight, its large yellow stars in hundreds glowing against a dark background of evergreens. *Dicentra spectabilis* is also very decorative when well grown, but as it becomes unattractive when the flowers are faded, it is well to arrange the border so that plants later in making their growth, such as Michaelmas Daisies, perennial Sunflowers or the like, should hide the *Dicentras* during the latter portion of the summer. Lupins, white, blue and purple, are at their best in May, while by the water blue Monkshood and Solomon's Seal flourish abundantly, the latter also growing on the banks in the wild garden with wood Hyacinths and Stars of Bethlehem. The yellow Day Lily (*Hemerocallis flava*) blooms throughout the month; the flowers, as evanescent as their faint perfume, closing after one day's life, but the scapes are many-blossomed and the individual deaths are scarcely noticed.

Beneath a tall specimen of *Aralia spinosa*, that throws out a spread of Palm-like leaves, white Violas mingle with hybrid *Aquilegias*, the combination of colours in some of the latter being most exquisite. The strongest seedlings, which are the earliest to bloom, may generally be pulled up and consigned to the rubbish heap, as they usually produce coarse, double flowers. Those that come later are often of exceptional delicacy, both of form and colour; dark yellow corollas contrasting with violet or red perianths, white with blue—gradations of pale pink, cream, silvery grey, faintest saffron and dead white—very poems of colour; while the shapes are equally diverse and pleasing—some with the spurs long, slender and straight, others with the extremities turning inwards, giving the effect of the bird-neck of dove (Columba) or eagle (Aquila), from which the flower takes its dual names.

The Lily of the Valley beds have never before given such a bountiful supply of bloom, tall, large-belled spikes having been gathered by the handful for indoor use, the rooms and passages of the house being filled with their delicate fragrance. One of the sweetest scented flowers that blows—the old double white Rocket—is also a May, or rather a May and June flowerer. A clump of a dozen plants has thrown up fine heads of bloom amongst a colony of *Geum coccineum*, the scarlet of whose flowers sets off the lavender-tinted white of the Rockets. On an evening after a shower this corner of the garden is absolutely filled with perfume. Rockets are now seldom grown in the gardens of the rich, but are often to be found in abundance in those of the poor, the cottager's taste being conservative in garden matters. A space of the rockery has been covered with the *Gentianella's* blue of blues, while *Aubrietias*, *Alyssum*, *Rockfoils* of many kinds, *Veronica prostrata*, *Mimulus* and *Myosotis palustris* have added their varied tints to the green of the young Fern leaves and the red-grey of the stones. At the foot of the rockwork, where the water runs away in a cup-shaped hollow, the variegated Water Flag grows, and is in the spring a striking object. With the advent of summer, however, the variegation is lost, but the broad, sword-shaped leaves are always handsome. A *Wistaria*—whose trunk is as thick as a man's leg—which rambles along the top of an old wall 60 feet in length, has roofed the Lichen-covered stones with pale purple scented flower-eaves fully 2 feet deep. *Laburnum*, lilac and pink Thorn have bloomed profusely, as has *Choisya ternata*, which seems totally uninjured by the past severe winter. Single *Deutzia* and *Guedler Rose* have also blossomed well; *Clematis montana* and *Honeysuckle* festooning arches and wreathing the trunks of some old hollow trees with the delicate tracery of

their flowering tendrils. A large-flowered white *Clematis*, possibly *alba magna*, which has mingled with the *Devoniensis* by the porch, has usurped almost the whole of the trellis for the display of its great stars, which have now ascended as far as the upper windows. Roses on the walls have been giving unsparing supplies of flowers. A *Safrano* on a southern exposure, from which a handful of perfect buds was picked on December 30, was the first to bloom, commencing on May 2. Then in quick succession came yellow and white *Banksian*, *Rève d'Or*, *Rubens*, *Niphetos*, *Gloire de Dijon*, *Devoniensis*, *Mme. Lambard*, and *Gloire Lyonnaise*, and on the 30th a beautiful *Mme. Lambard* from the open bed. Four varieties of Poppies have been in flower, clumps with a dozen or more great blooms of the giant Oriental Poppy (*Papaver bracteatum*) a blaze of vivid scarlet. The sight of this Poppy reminds one of Ruskin's words, "Wherever men are noble they love bright colour, and wherever they can live healthily bright colour is given them in sky, sea, flowers, and living creatures." The graceful Welsh Poppy (*Meconopsis cambrica*), with drooping yellow heads and deeply-fretted foliage, outlines year by year the rough stone edging of a portion of the wild garden, reproducing itself without interference. *Papaver pilosum*, a little-known Poppy, whose fragile brick-coloured blossoms are borne in great profusion throughout the spring and summer, is also a May subject, and being hardy and easily increased should be added to any collection not possessing

*Gypsophila cerastioides*.

it. The Iceland Poppies, orange, white, and yellow, make patches of colour here and there; patches whose edges have been irregularly widened by self-sown seedlings. It is, perhaps, to the *Paeonies* and the German *Irises*, however, that May should rightly belong, since these give but little of their splendour to other months. New Tree *Paeonies* are now raised in such quantities that one's favourites are soon elbowed out into the "general collection," but *fragrans*, *lactea*, *Louise Monchelet*, *Reine Elizabeth*, and *Triomphe de Vandermael* are all excellent varieties, carrying flowers of taking shades that dwarf those of the old *Paeony Moutan* into comparative insignificance. The herbaceous section are no less decorative, from the old double crimson and rose forms down to the pure single white flowers of *P. albiflora* and *P. Emodi*. German *Irises* have for the most part bloomed excellently, there having been an almost total absence of wind and rain to mar their petals. A pleasing effect has been obtained by the planting of a mass of *Iris flavescens* by the side of *I. pallida*, the light yellow of the former contrasting delightfully with the pale mauve of the latter. All the rest of the *I. germanica* section, twelve in all, flowered well with the exception of *I. Princess of Wales*, the best white, which, seemingly, has a poor constitution. *Bambusa viridi-glaucescens* is sending up strong shoots as proof that the winter has not harmed it, but the great standard *Magnolia grandiflora*, which bore over 200 flowers last year, will have none this.

In the warm spring evenings when the sunlight shone through the young green of the Beech leaves—which, indeed, is one of the most beautiful sights in Nature—when the woodquests sailed round in the still air or cooed to their mates in the immemorial Elms, and the cream-coloured doves darted swiftly across the lawn to the ivied Walnut tree in which they had built their first *al fresco* nest; when long shadows lay upon the Grass and the day was going to its perfumed rest, one counted those as lost hours that were not spent in the garden. S. W. F.

#### GYPSOPHILA CERASTIOIDES.

THE *Gypsophila* best known in gardens is the graceful spreading *G. paniculata*, so elegant when arranged with other cut flowers, but the family contains several other pretty species, one of which is here shown. *G. cerastioides* is a charming rock plant, only growing about 2 inches high, but spreading about in a pretty way, the slender shoots clothed with narrow leaves an inch or more in length, the flowers appearing in their axils in small clusters. They are about half an inch across and white, with slight streaks of violet. It comes from the north of India, is the finest flowered kind in cultivation, and a fast growing plant in a suitable open position. *G. prostrata* is also a charming species, of a trailing habit, its flowers, white or pink, borne in loose panicles late in summer.

#### BOOKS.

##### LES PLANTES BULBEUSES TUBERCULEUSES ET RHIZOMATEUSES ORNAMENTALES DE SERRE ET DE PLEINE TERRE.\*

THIS is very well done by a practical man. The cultivation of these plants is dealt with in the first place, and the rest of the work is an alphabetical arrangement in which generally a very sufficient account of each plant is given. It is a useful little book, and will, we hope, be duly translated into English at no distant date. If we have any fault to find, it is with the names which are given under some of the cuts, and which would lead to some confusion, as, for instance (p. 374), *Iris reticulata* is not properly named after M. Dammann. As an example of the author's method we take the genus called *Crinum* (p. 176):—

*CRINUM* (Linn., *Crinole amaryllidées*; *C. abyssinicum*, Hochst.; *Abyssinia*, 1892).—Leaves long, erect, stalk stout, 16 inches to 24 inches in height, ending with an umbel of from six to eight horizontal-limbed white flowers; the pipe is arched and about 4 inches to 6 inches in length. A very handsome plant.

*C. AFRICANUM*.—*Vile Agapanthus umbellatus*. *C. AMABILE* (Don., *C. superbum*, Sumatra, 1810).—Medium sized bulb, the neck long. Leaves erect and lance-shaped, in length 1 yard to 1½ yards, and in breadth 4 inches to 4½ inches; the stalk, from 32 inches to 1 yard, is depressed and bears an umbel of fifteen to twenty strongly perfumed flowers; the pipe is 4 inches to 4½ inches long and bright red, the limb of equal length and rose-pink. It is a summer-blooming hothouse plant.

\* "Les Plantes Bulbeuses, Tuberculeuses et Rhizomateuses Ornamentales de Serre et de Pleine Terre." Par D. Guichenot. Avec 227 figures. Octave Doin, 8, Place de l'Odéon, Paris.

*C. AMERICANUM* (Lin., Centr. Amer., 1752).—Oval-shaped bulb, the neck short; leaves arched and from 28 inches to 36 inches in length; the stalk from 20 inches to 28 inches, terminating in an umbel of four to six white sweet-smelling flowers; the pipe 4 inches to 4½ inches in length, with limb of same length. A summer-blooming hothouse plant.

*C. AMENUM* (Roxb., India, 1807).—Round thick bulb. A summer-blooming hothouse plant with very sweet-scented pure white flowers, the pipe a greenish rose colour.

*C. AQUATICUM* (Burch.).—*Vide C. campanulatum*.  
*C. ASIATICUM*, Lin., *C. toxicarium*.

*C. DECLINATUM* (Trop. Asia, 1732).—Thick bulb, 4 inches across by 6 inches to 8 inches long; the leaves each a yard in length; stalk depressed, 20 inches to 24 inches and terminating in an umbel of twenty flowers; the pipe greenish and 4 inches in length, the perianth white. Greenhouse plant and also hardy.

*C. AUSTRALE*.—*Vide C. pedunculatum*.

*C. BALFOURI* (Baker, Secotra, 1880).—An October-blooming greenhouse plant with sweet-smelling pure white flowers.

*C. BROUSSONETTI*.—*Vide Amaryllis Broussonetti*.

*O. CAFFRUM*.—*Vide C. campanulatum*.

*C. CAMPANULATUM* (Herb.), *C. aquaticum* (Burch.), *C. caffrum* (Herb.), the Cape, 1817.—Oval-shaped bulb, the leaves a yard long, the stalk 24 inches long and terminating in an umbel of from five to six flowers of a brilliant red colour. A hardy plant, but difficult to bloom.

*C. CANALICULATUM*.—*Vide Amaryllis pedunculata*.

*C. CANDELABRUM*.—*Vide Amaryllis orientalis*.

*C. CAPENSE*.—*Vide C. longifolium*.

*C. CAREYANUM* (Herb., Mauritius, 1821).—A very thick globe-shaped bulb, the leaves and stalk each 12 inches long, terminating in an umbel of five to six white flowers, with reddish stain. Hothouse and greenhouse plants, blooming in autumn.

*C. COLENSOL*.—*Vide Crinum Moorei*.

*C. DECLINATUM*.—*Vide C. asiaticum*.

*C. DISTICHUM* (Herb., Sierra Leone).—Small-sized bulb, leaves and stalk each 12 inches long, very large single flowers in summer, 8 inches in length and a bright red colour, grown in the greenhouse with a moderate temperature.

*C. ERUBESCENS* (Ait., Trop. Amer., 1780).—Globe-shaped bulb, leaves 32 inches and stalk 24 inches in length. A greenhouse plant, producing in summer an umbel of ten to twelve flowers, a purple-red colour.

*C. FALCATUM*.—*Vide Amaryllis falcata*.

*C. FORBESIANUM* (Herb.), *Amaryllis Forbesi* (Lindl), Delagoa, 1824.—Very thick bulb, 6 inches to 8 inches in diameter, the leaves from 1 yard to 1 yard 10 inches, the stalk 24 inches long. A greenhouse plant, blooming in October, producing umbels of thirty to forty very large, white, highly-scented flowers, reddish on the outsides.

*C. GIGANTEUM*.—*Vide Amaryllis ornata*.

*C. HERBERTIANUM*.—*Vide Amaryllis ornata*.

*C. KIRKI* (Baker, Zanzibar, 1879).—Globe-shaped and very thick bulb, the leaves 1 yard and the stalk 20 inches in length. A hothouse plant, blooming in October and bearing an umbel of fifteen to twenty very long, white, rose-tinted flowers; the pipe greenish and the limb deflected.

*C. LONGIFLORUM* (Herb.), *C. capense*, *Amaryllis longifolia*, the Cape, 1816).—Very thick bulb with the neck much extended; leaves glaucous, numerous, and a yard long; the stalk of equal length. Blooms in July and August, producing an umbel of twelve to fifteen large, sweet-smelling, infundibuliform (?) white flowers, the outer parts being rose colour. This is the hardiest of all the *Crinums*.

*C. LONGIFLORUM ALBUM*.—A variety of the preceding, having pure white flowers. This is one of the finest of the hardy species and no garden should be without it. Plant in deep light soil on a warm situation. In winter surround the bulb with sand and cover with dry leaves or Moss. Increased by division of the bulbs, which root in pots in beds.

*C. LONGIFOLIUM*, Thunb.; *Amaryllis longifolia*, Linn.; the Cape, 1752.—Very thick bulbs; the leaves 20 inches to 1 yard in length. Stalk 12 inches to 20 inches. A very beautiful plant, bearing in summer eight to ten flowers, stained red, 3 inches to 4 inches in length, with pipe of same length. Culture: plant in the open air like *C. longiflorum*.

*C. MACKENI*.—*Vide C. Moorei*.

*C. MACOYANUM*.—*Vide C. Moorei*.

*C. MACOWANI* (Baker, Natal, 1874).—Bulb 8 inches to 10 inches in diameter, leaves 32 inches to a yard in length, stalk 1 yard. Flowers in November, producing an umbel of twelve to fifteen large-sized scented flowers, each 6 inches to 8 inches long, and white tinged with purple. It is best grown in a pot, having regard to the lateness of its bloom.

*C. MAKOYANUM*.—*Vide C. Moorei*.

*C. MOOREI* (Hook.), *C. Colensoi*, *C. Mackeni*, *C. natalense*, *C. Makoyanum*, Natal, 1874.—Thick bulb, the neck long; leaves a yard long, stalk 24 inches long; summer-blooming, producing an umbel of eight to ten flowers; the stalk long and greenish; perianth white and stained red. Requires the same treatment as

*C. LONGIFLORUM*, *C. natalense*.—*Vide C. Moorei*.

*C. NERVOSUM*.—*Vide Eurycyclus amboinensis*.

*C. ORNATUM*.—*Vide Amaryllis ornata*.

*C. PEDUNCULATUM* (R. Br.), *C. australe*, *C. canaliculatum*, *C. taitense*, Australia, 1790.—Thick bulb, leaf a yard long, stalk 32 inches; summer-blooming greenhouse plant, producing umbels of twenty to thirty flowers; the pipe greenish, wide opened white segments.

*C. PETIOLATUM*.—*Vide Amaryllis ornata*.

*C. POWELLI*.—A hybrid of *C. longifolium* and *C. Moorei*; flowers reddish; grown in the greenhouse for trial out of doors.

*C. PURPURESCENS* (Herb.), Fernando Po, 1826.—Oval-shaped, medium-sized bulb, leaves 28½ inches long, stalk 12 inches; a summer-blooming hothouse plant, producing an umbel of six to eight wine-red flowers.

*C. REVOLUTUM*.—Hybrid; medium-sized delicately tinted flowers; the pipe long and white, each petal divided in the middle by a violet-rose-coloured stripe. Blooms in August.

*C. RIPARIUM* (Herb.), *Amaryllis cinnamomea*, W. Africa.—Leaves 32 inches to a yard long, undulating, and tinged with red; stalk 1 yard; bears an umbel of fifteen to twenty highly odorous flowers of deep purple colour, edged with white. Cultivate in the greenhouse for trial in the open air.

*C. ROOZENIANUM* (O'Brien, Jamaica, 1881).—Flower red outside and white within. For the hothouse.

*C. SANDERIANUM* (Baker, Sierra Leone, 1884).—Brown Pear-shaped bulb, 4 inches in diameter, and neck long; leaves few and close; stalk depressed, 20 inches long, terminating in an umbel of four long-petalled white flowers, 6 inches to 8 inches long, the divisions narrow and the centre stripe a brown-purple. Under glass, with moderate temperature. Time of bloom not fixed.

*C. SPECIOSUM*.—*Vide Amaryllis purpurea*.

*C. SUPERBUM*.—*Vide C. amabile*.

*C. TAITENSE*.—*Vide C. pedunculatum*.

*C. VANILLAGORUM*.—*Vide C. giganteum*.

*C. YEMENENSE*.—Bulb very thick, with long neck; leaves numerous, waving, and a yard in length; bears in summer on a stout stalk ten to twenty flowers, the pipes of which are very long. In winter under glass, with moderate temperature or greenhouse; in summer, the open air.

*C. YUCIFLORUM*.—*Vide Amaryllis Broussonetti*.

*C. ZEYLANICUM*.—*Vide Amaryllis ornata*.

*C. TOXICARIUM*.—*Vide C. asiaticum*.

HOTHOUSE SPECIES.

Plant in roomy pots on free, sandy, light, but rich dry soil. After the plant has rested keep the atmosphere warm and humid; apply a little liquid manure on the appearance of the floral stems. The bloom is of very long duration. When the flowers begin to fade decrease by degrees the waterings and keep the plants compara-

tively dry for two months, not, however, to the extent of making them suffer. This period of repose is necessary to assist the development of the floral stems. Re-pot every two years at the end of the period of repose. These beautiful plants bloom in summer, but at no fixed time, as the flowers can be produced at all seasons by cultivation more or less forced. The period of bloom lasts longer if after the flowers are fully open the plants be transferred from the hothouse to a more temperate atmosphere.

OUT OF DOORS.

The hardy species are grown like *Amaryllis vittata*, *i.e.*, care being taken to plant well apart and to cover the bulbs in winter with sand, Moss, or dry leaves. Increase by division of the bulb, taking care to preserve some of the root to each division, and when sufficiently strong place in pots in beds until they strike root. Some species give very few bulbs, and in this case recourse must be had to seed. These, which are large, must be sown separately in pots large enough to avoid disturbance of the roots in planting out. When the seedlings are strong enough they are again placed in pots at intervals of time and transferred to the temperate house for treatment as fully grown plants. The roots of *Crinums* ought never to be cut.

Horses, Asses, Zebras, Mules and Mule Breeding.\*

—The many books that have been written on the equine race have by no means exhausted the subject, and the existence of the present work is well justified by its contents. The outcome of the authors' labours has been to collect, in one handy volume of some 160 pages, results of the experiences of recent travellers respecting the history and habits of species hitherto imperfectly known and generally thought to be unamable—species like Prefevalski's horse and Grevy's mule, which have recently been impressed into the service of man, and from which new and valued hybrids have been obtained. But chiefly the authors have succeeded in supplementing the very scanty knowledge which has hitherto obtained in England in remarkable contrast to other civilised countries regarding the great value and economy of the mule as a beast of draught and burden for agricultural purposes as well as others. In this respect the authors may be congratulated on having produced a work of great practical interest and value. The book, which is well printed and illustrated with some excellent engravings, has an appendix containing a memorandum on "Mule Breeding in India."

The American Chrysanthemum Annual.†

—One of the American gardening papers, when reviewing the recently published Year-Book of the National Chrysanthemum Society, called attention to the necessity for some such publication in the States, where the Chrysanthemum claims almost as much attention as it does in this country. Mr. Barker's annual is an entirely new venture, and one that is executed in a very creditable manner and contains much that will interest American and English growers alike. Portraits of eminent authorities are given, the frontispiece being that of Mr. John Thorpe, the father of the Chrysanthemum in America. Some full-paged illustrations of new seedlings also embellish the work, the celebrated Japanese incurred Philadelphia being, of course, included. Many of the writers and the topics selected are, of course, American, but the editor has adopted a comprehensive programme and obtained reports from eminent growers and authorities in different parts of the world. Thus, we find England represented by Mr. C. E. Shea, Mr. Shoemith and Mr. Harman-Payne, Belgium by M. O. de Meulenaere

\* "Horses, Asses, Zebras, Mules and Mule Breeding." By W. Tegetmeier and C. L. Sutherland. Horace Cox, Field Office, Bream's Buildings, E.C.

† "The American Chrysanthemum Annual." By Michael Barker. Mayflower Publishing Company, Floral Park, New York.

(than whom perhaps no one is better qualified to speak), Australia by Mr. H. J. Carter, of Sydney, New Zealand by Mr. John Dutton, and Canada by Mr. Ewing. There are two illustrated articles on diseases of Chrysanthemums, besides historical and cultural papers. A list of new seedlings for 1895 is also given. The price is one dollar.

## TREES AND SHRUBS.

### THE WAX MYRTLE.

(MYRICA CALIFORNICA.)

THE Wax Myrtles are desirable for the garden, for though not effective as flowering shrubs, they possess a most delightful spicy fragrance. Our native species, *M. Gale*, should find a place in every collection of sweet-smelling plants, and we find it free and vigorous in close wet soil where few things would succeed. It loses its leaves in winter. The Californian Wax Myrtle is evergreen, retaining its fragrant leaves throughout the winter. It makes a handsome bush in England, but is rarely seen outside of botanical collections. The illustration here given is of a fruiting branch, and Mr. Burbank says that in California this species is an upright growing tree, the trunk often attaining a diameter of from 1 foot to 2 feet.

***Sambucus racemosa plumosa aurea*.**—This promising variety of the scarlet berried Elder (*Sambucus racemosa*) received an award of merit at the R.H.S. meeting on May 14. The cut-leaved variety of *S. racemosa* has been grown for some years under the names of *serratifolia* and *plumosa*. The newer kind is a counterpart of this last, except that the foliage is of a pleasing yellow tint, and it is mere than probable that as the season advances it will (as with the golden-leaved variety of the common Elder) acquire a much deeper hue. In any case it bids fair to be a valuable addition to golden-leaved shrubs, as it appears to be equally vigorous with the typical kind. In rather poor soils fully exposed to the sun these Golden Elders are seen at their best, and, unlike some other golden-leaved shrubs, they are more effective after Midsummer than they are before that time. Of the common Elder there are several varieties remarkable for foliage distinctions, notably *variegata*, the leaves of which are marked with white; *heterophylla* and *laciniata*, two cut-leaved forms; and *rotundifolia*, with rounder leaflets than those of the ordinary kind.—T.

***Pterocarya caucasica*.**—Our large specimen of the above-named tree has for several years apparently grown so fast that I was induced the other day to hunt up the note and accompanying illustration published in THE GARDEN in 1888 with the view to ascertain what progress had actually been made. I find the spread of branches was therein given (and the measurement was an accurate one) as 75 yards; at the present time it is exactly 90 yards, a convincing proof, I think, that, given a favourable soil and situation, it grows, for an old tree, at a phenomenal rate. The extremities of the lower branches on all sides, being so far from the stem, have dropped close to the ground, helped thereto by the wealth of foliage and the long, heavy catkins, some of which this year are more than 20 inches in length and studded nearly throughout with the curious nail-like appendages. I think this is one of the most beautiful of all exotic trees; certainly one might travel many miles before finding anything to approach it in its grand symmetrical proportions, its fine foliage and unique fruit. The restrictive measures which on more than one occasion I have been compelled to adopt to keep the roots from encroaching on Vine and hardy fruit borders have seemed to give it new life, and I am inclined to think when next the trenches are opened we

shall find them a mass of fibrous roots. It is a pity the tree was planted on the site it occupies, but I imagine the planter had not the slightest idea it was likely to attain its present dimensions. If any GARDEN readers have seen the tree in its native habitat, the valleys of the Caucasian range, perhaps they will kindly give a little information respecting it.—E. BURRELL, *Claremont*.

***Rhododendron Smirnowi*.**—I was pleased to see that this distinct *Rhododendron* was flowering at Kew, and would like to ask if any reader of THE GARDEN has up to the present flowered *R. Ungerni*, which was introduced at the same time? Our plants were obtained from seed sent by the late Dr. Regel, so that they should be correct, but there is

The Wax Myrtle (*Myrica californica*). From a photograph sent by Mr. L. Burbank, Santa Rosa, California.

a very great resemblance between the two. The plants of *R. Smirnowi* are characterised by a more sturdy habit of growth, while the young leaves are covered on the undersides with a dense woolly tomentum of a dazzling whiteness, which changes to a browner tint on the adult foliage. In *R. Ungerni* the leaves are somewhat longer and the tomentum is a little less dense, while the plant does not branch so freely as *R. Smirnowi*. As figured in the *Gartenflora* some eight years ago or more, the flowers of *R. Smirnowi* are red, and those of *R. Ungerni* white. Not having induced our plants to flower yet, I cannot speak with certainty as to the correctness of their nomenclature, but feel confident that those grown as *R. Smirnowi* are quite correct. Concerning *R. Ungerni*

there is a doubt in my mind; hence, if any correspondent of THE GARDEN has flowered it, I should feel greatly obliged for the information.—H. P.

***Weigela Eva Rathke*.**—Among the first flowering *Weigelas* is the old *W. rosea* and its improved variety *Abel Carrière*; then afterwards we have a great many of the darker flowered forms. The flowers of these are as a rule not so widely expanded as those of *W. rosea*, but in some cases they possess the merit of flowering continuously for some time. One of the best of this group is *W. Eva Rathke*, whose blossoms are of a bright red tint and borne in great profusion. It forms a neat-growing bush, and is, like all of its class, perfectly hardy. So continuously does this flower, that when it was shown in such good condition as to be awarded a first-class certificate the summer had almost left us, for it was then the end of August, and *Clerodendron trichotomum*, always regarded as an autumn-flowering shrub, was at that time in full bloom. *W. Eva Rathke* is just now laden with blossoms, so that if a scattered succession is kept up till the end of August it will be a valuable shrub. Another long-flowering variety is *Gloire des Besquets*, which is of a paler hue than the preceding; and of white-flowered forms *W. candida* is the most persistent. All *Weigelas* have been remarkably fine this season. Where it is intended to propagate any of the *Weigelas* this is a very good time to increase them by cuttings, which should be formed of the young growing shoots (not the most vigorous ones) dibbled into pots, pans or boxes of sandy soil, and placed in a cold frame and kept close and shaded when necessary till rooted.—T.

***Azalea mollis*.**—There are a few things that everyone who is commencing to stock a garden with hardy flowers should lose no time in planting. Some of our best hardy flowers grow so rapidly that one may expect to see them at their best in the course of two or three seasons, but it is not so in the case of such things as *Paeonies*, *Hepaticas*, *Hellebores*, *Azaleas*, &c., which, being comparatively slow of growth, are some years before they yield the full measure of their beauty. Nothing can be finer than good-sized specimens of *Azalea mollis* when in full bloom, but unless one begins with fair-sized specimens, one must wait a decade or more to see them really effective. In Mr. G. F. Wilson's garden at Weybridge there are some plants which this year were wonderfully effective. They were planted about twenty years ago, and, soil and situation being congenial, they have formed handsome specimens some 8 feet high and of proportionate breadth. These hardy *Azaleas* are quite as beautiful and as effective as their relatives of the greenhouse, and so hardy and enduring, that the severest winter does not harm, and time heightens their beauty. They are gorgeous when massed, but I like them best when they are so far isolated that each plant can develop without contact with its neighbours.—J. C. B.

**Notes from Chester.**—The full wealth of summer glory now presses itself to the front, and the foliage damage for which the frost was responsible is now scarcely to be detected anywhere. The delicacy of the spring foliage is followed by such an abundance of floral beauty, that the season seems to be one of the richest through which we have passed for many years. We send you a few sprays from some of the more prominent flowering shrubs. *Viburnum plicatum*, with its masses of bloom, big petals, like the *Hydrangas*, and bold deep-coloured foliage to set off the showy inflorescence, is a charming plant in its place in the open, and just now, with the *Philadelphus*, commanding the attention of those who come within sight of it. We send a spray of *Philadelphus coronarius aureus* to bear out what we say. Delicately indeed is the beautiful *Spiraea Reevesiana*, with its *Deutzia*-like double flowers. There are many other free-blooming white-flowering shrubs beautiful just now, but to give some colour variation we have sent a spray of *Colutea arborescens*, an excellent shrub for town planting,

and *Robinia hispida rosea*, which is most distinct, its great flowered pink tresses hanging thickly and gracefully from its branches. *Weigela Stelzneri* is a charming feature in the shrubbery. Its flowers are bold in form and rich in colour. Roses and Irises fill wide breadths of garden ground with gorgeous colour, and here and there seas of flame mark the beds where the Poppies grow.—DICKSON, *Chester*.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

JUNE, 11.

TAKING into consideration the fact that only three weeks have elapsed since the splendid display at the Temple Gardens, it is surprising that such a magnificent exhibition should have been brought together in the Drill Hall on Tuesday. Three tables stretched through the Hall, and on either side were two others, all crowded with a great diversity of exhibits. Another most pleasing fact was the large attendance. Such a gathering as that of last Tuesday clearly shows the necessity for more commodious premises, where not only the light is better, but also the surroundings. The success of these fortnightly gatherings have now exceeded the most sanguine expectations of their promoters.

Having regard to the late specially fine exhibition of Orchids at the Temple Gardens from both trade and private growers, it would not have seemed at all out of place had there been but a few on this occasion. This, however, was not so, for it was in many respects one of the finest, if not the very finest, displays of these flowers ever seen in the Drill Hall. Proportionately more certificates were awarded than at the Temple show, and some few most decided acquisitions were to be noted, prominent amongst these being the pure white form of *Cypripedium bellatulum*. Two other notable exhibits that received the higher award were *Cattleya superba alba* (of white forms of coloured species there appears to be no end) and *C. gigas Sanderæ*, of intensely deep colour. The medal awarded at this meeting to the best hybrid Orchid not yet in commerce was given to *Phaius Cooksoni*, a paler hybrid than *P. Owenianus* and scarcely so beautiful. Of specimen Orchids, particular note should be made of *Lælia purpurata Schrederæ*, of which a large specimen was staged in rude health; another of *Dendrobium thyridiflorum* was of unusually rich colouring, whilst of *Cattleyas* there were several good specimen plants. A small specimen was shown of *Cypripedium caudatum Wallisi*, every growth of which was flowering.

Hardy cut flowers were strongly represented, *Pæonies* being to the fore. Tea-scented *Roses* were of splendid quality. Two notable plants were those of *Blandfordia aurea*, of which a superb example was sent, also of *Carpenteria californica*. Several choice foliage plants were shown, including a grand specimen of *Dracæna Sanderiana*, exhibited by its introducers.

Fruits were chiefly represented by early Strawberries in fine examples, two very promising new Melons, both from one source, and by well coloured Lord Napier Nectarines. Vegetables comprised a large number of well-ripened Tomatoes, several fine dishes of Peas and Cauliflowers, with other early produce from under glass and the open air.

#### Orchid Committee.

First-class certificates were awarded to the following:—

*CIRRHOPELALUM ROBUSTUM*, an extra fine species, more robust than many and far more interesting in point of colour, which is a pale golden shade, with a soft suffusion of green, the labellum being of a dark maroon tint. The spike bore eight flowers; the bulbs are stout and fleshy. An introduction from New Guinea. From Messrs. James Veitch and Sons.

*CATTELEYA SUPERBA ALBA*, a white form of this richly-coloured species; the sepals and petals are milky white, with a perceptible trace of green on the reverse; the lip also is white, there being a slight touch of pale citron colour on its central part. From Mr. Thos. Statter.

*CYPRIPEDIUM BELLATULUM ALBUM* was beyond any question the most remarkable exhibit in the Hall. It is a pure white form, without spot or colour of any shade, being a truly white variety of the species, having the form of its best varieties, with great breadth of petal, whilst the lip is slightly elongated—quite a gem. From Sir F. Wigan's collection at Clare Lodge, East Sheen.

*CATTELEYA GIGAS SANDERÆ*.—A superbly coloured form of this fine species, more deeply shaded than any variety previously shown. The sepals and petals are of a deep rosy mauve, the latter a darker shade, being also notable by their breadth; the labellum, as in all forms of *C. gigas*, is a notable feature, the colour being greatly intensified, a rich vinous-purple tint, with the edge beautifully fringed, the blotches on either side of the throat being very conspicuous and the golden veining well defined. From Mr. Hamar Bass, Burton-on-Trent.

Awards of merit were adjudged to the following, viz.:—

*RENANTHERA IMSCHOOTIANA*, which, compared with the older, but still all too scarce *R. coccinea*, is of quite dwarf and compact growth. The plant in question bore but nine leaves, each some 4 inches long, the entire plant no more than 6 inches in height, yet it bore a handsome arching spike of fourteen flowers, sanguinous-red in colour, and of good size, with the peculiar form seen in this genus. The species in question is very rare, there being but two plants known to be under cultivation. From Mr. Ed. H. Woodall, St. Nicholas House, Scarborough.

*LÆLIA GRANDIS* (Wigan's var.).—A very distinct form of the type, with the flowers scarcely so large, but of handsome colouring, the sepals and petals being of old gold colour, the lip having reddish purple veins on a pale terra-cotta-pink ground. From Sir F. Wigan.

*LÆLIA PURPURATA RICHMOND GEM*.—A very fine form with flowers of extra size and vigour; the sepals and petals white, with but a very slight flush, the lip larger than usual and of an intensely deep purple, having the beautiful markings as seen in *L. purpurata Brysiana*. From Sir F. Wigan.

*CYPRIPEDIUM ELENOR* (*C. selligerum majus* × *C. superbians*).—Another specially fine hybrid with broad drooping petals, freely spotted, the dorsal sepal large and well marked, somewhat after *C. Lawrenceanum*. Two spikes bore two flowers on each, which were of massive proportions. From Sir Trevor Lawrence.

*CYPRIPEDIUM FRACIDA BRANDT*, an exceedingly fine and interesting hybrid, inasmuch as both of its parents are themselves hybrids, the one being *C. Io-grande* (*C. Argus* × *C. Lawrenceanum*), and the other *C. Youngianum* (*C. superbians* × *C. Roebelini*). The flowers are unusually large and of fine proportions; the petals retain the peculiar spotting characteristic of *C. Argus*, are 4 inches in length, of drooping form and of extra breadth, the ground colour a metallic pink. The dorsal sepal takes after *C. Lawrenceanum*, but is somewhat of a lighter shade, suffused with a bronzy purple hue, being angular in shape; the lip is of extra size and as prominent as in *C. Curtisii*. From Messrs. Sander and Co.

The special prize—offered on this occasion for the best seedling Orchid not exhibited previous to January 1, 1895—was adjudged to—

*PHAIUS COOKSONI* (*P. Humbloti* × *P. grandiflorum*), which has much of the habit and character of *P. Owenianus* (another fine hybrid), the flowers and growth being thus far of similar proportions. The sepals and petals are of a pale terra-cotta pink, self-coloured, the lip being broad, with the lower portion of a deep rose tint and the sides of a bronzy red. It was awarded a silver-gilt Flora medal. From Mr. Norman Cookson, Wylam-on-Tyne.

Botanical certificates were given notably to the five following species of *Masdevallia*, all belonging to the dwarf section of the genus: *M. campyloglossa*, *M. gemmata*, very minute; *M. Wagneri*, small yellow; *M. muscosa*, singularly pretty; and *M. demissa*. All from the collection of Mr. R. J. Measures. The same award was made to *Scuticaria Hadweni*, greenish yellow and brown, the lip pale rose, and *Oncidium insculptum*, a pretty, if not showy species, both shown by Mr. Walter C. Walker; and to *Sarcanthus Williamsoni*, growth very dwarf, the spike bearing small dark flowers, and *Bifrenaria vitellina*, both coming from Messrs. W. L. Lewis and Co.

Messrs. Sander and Co. showed a remarkably choice group, effectively arranged, with well-grown foliage plants. It comprised four large masses of *Odontoglossum vexillarium*, some with deep rosy pink shades, and others of lighter tints, but all fine varieties; one of the lighter kinds named *F. W. Moore* had flowers of fine proportions. *Lælia Lucasiana* was quite a miniature, with rosy purple flowers, the lip being a pale golden self, each blossom would not be more than 1½ inches in diameter. *Cattleya gigas* was shown of extra quality, notable both for the breadth of the lip and the deep colouring. *Phaius Owenianus*, a richly coloured hybrid, was present, also *Cypripedium Svend Brun* (*C. Lowi* × *C. Curtisii*), a noteworthy hybrid, retaining in the main the features of *C. Lowi*, but darker in colour. *Oncidium serratum*, a fine specimen, was shown full of bloom, its dark flowers being almost as large as *O. macranthum*. *Cattleya Mossiæ* was represented by one particularly fine variety, in which the rosy purple of the lip was almost supplanted by a rich shade of deep golden yellow, being most effective; *Thunia Veitchii magnifica*, with white, slightly flushed sepals and petals, and the lip somewhat darker, with old gold and pale purple markings, and a stout growth; *Thunia Beauonia grandiflora*, one of the parents of the latter, was also shown. Of *Angraecum Fournierianum* a good example was to be seen; the failing in this species appears to be that of casting its terminal flower buds. *Epidendrum vitellinum majus*, a mass in profuse flower, and a grand plant of *Lælia grandis tenebrosa* were both striking, the latter being rarely seen so good. *Dendrobium Johnsonæ* was shown in good condition; it is a singular looking, but handsome species with pure transparent white flowers, the sepals narrow and pointed, the petals broad and arrow-shaped, the lip marked towards the throat with dark purplish veins; the spikes are erect, being produced freely upon the old bulbs. *Cypripedium Numa* (hyb.) in the way of *C. Stonei*; *Sobralia Veitchii rosea*, a charming species, possibly the finest of all the genus, with a pale rosy purple lip of great breadth, the sepals and petals a light rose; *Odontoglossum lateo-purpureum*; *O. mulus splendens* and *O. hystrix* each had fine spikes in excellent condition; *O. crispum* in one instance was represented by a singularly distinct form, with the sepals blotched with pale oak colour, the petals being pure white (very fine); *Sobralia Kienastiana*, pure white with pale lemon colour in the throat; *Masdevallia Veitchii* and *Vanda teres* with *Aerides expansum* were all included in this exhibit; also *Anguloa eburnea*, *Dendrobium Phalanopsis Schrederianum*, *Cattleya dolosa*, and *Masdevallia Rozii*. A silver-gilt Flora medal was awarded.

Messrs. J. Veitch and Sons had a good exhibit, comprising several of their unique hybrids. Amongst these were beautiful examples of *Disa Veitchii* and *D. Langleyensis*, also *Lælia-Cattleya Canhamiana*, a hybrid between *Cattleya Mossiæ* and *Lælia purpurata*, and *L. C. Arnoldiana*. Note should also be made of the fine forms of *Lælia purpurata*, one extra good, a most vigorous plant; *Cypripedium Clonius*, a distinct and beautiful hybrid of the *Selenipedium* section; *Angraecum falcatum*, a good mass, with numbers of its small pure white flowers; *Cypripedium Stonei* with four flowers on the one spike; *Odontoglossum cordatum*, very good, with several spikes; *O. Pescatorei*, *O. vexillarium* and *O. crispum* in variety; *Cypripedium superbians*, extra fine;

*C. selligcrum majus* and *C. Lawrenceanum* Hyenanum, bearing one flower; and *Dendrobium Dearei*, with a large spike of bloom. Other noteworthy things were *Cattleya Mossia* and a beautiful form of *C. Mendeli*, (*Cattleya Warszewiczii* (*C. gigas*), a good plant, with *Cypripedium philippense*; *Oncidium macranthum*, a fine variety; *O. superbiens*, *Cypripedium Hookerianum* var. *volanteanum*, with cut blooms of *Cattleyas*, *Sobralias*, and *Vandas*. Award silver-gilt Flora medal.

Mr. Guiney Fowler, South Woodford, Essex, had a nice group containing a grand specimen of *Laelia purpurata* Schrodere with eight spikes, each bearing four large blooms; the purest of white sepals and petals, with the very faint rosy lilac veins on the otherwise white lip make this one of the choicest light forms of this species. *Dendrobium thyrsoiflorum* was another fine specimen plant with nine large spikes of bloom, each bearing flowers of extra size, there being more colour than usual in the lip. *D. Falconeri*, rarely seen, was represented by a small, but profusely-flowered and healthy example. Another form of *Laelia purpurata* was shown, with a distinct white splash upon the lip. *Odontoglossum crispum* was extra good, so also were *Laelia grandis tenebrosa* and *Cattleya Mendeli*. *Thunia Bensonae* was staged well, likewise *Cattleya Warneri*, richly coloured. *Phaius Owenianus* was here represented by a superb spike of intensely deep colour in the blossoms. *Cypripedium Lawrenceanum*, *C. caudatum*, and *C. Lowi* were comprised, also two good healthy plants of *Aerides Fieldingi*, each bearing a branching spike; this group was well arranged with light Grasses, and a silver Flora medal was awarded.

Messrs. Hugh Low and Co. staged a good group in their characteristic style, *Cattleya Mossia* being represented by several plants of the finest forms. *Dendrobium superbiens* (*maeranthum*), of rich colouring, and *Odontoglossum Roezli* in varieties were both seen to good advantage; so also were *Cypripedium Curtisii* and *C. Curtisii viride*, a pale form, suffused with light green. *Oncidium carthaginense*, an uncommon species, and *Odontoglossum vexillarium* were shown with a beautiful hybrid in *Laelia-Cattleya Ingrami*, very dwarf in growth, but bearing two large flowers, with the lip of a deep velvety purple and the sepals and petals light rosy purple (silver Flora medal).

Messrs. B. S. Williams and Son sent a bright group, in which *Dendrobium suavisimum* was extra good; *Cypripediums* were fine in masses full of flower, and *Epidendrum vitellinum majus* was in good form; *Pseudea* were represented by *P. Lehmanni*, *P. Roezli* and *P. Roezli rosea*, the latter quite distinct; *Cattleya Aclandiae* was here to be seen, also *Stanhopea Amesiana*, the beautiful creamy white species; *Aerides Houlettianum* and *Laelia grandis tenebrosa*. A silver Banksian medal was awarded.

Mr. Pitt, Stamford Hill, again staged an excellent group, in which were well-coloured forms of *Laelia grandis tenebrosa*, some with the sepals and petals of a dark coppery shade, and others of a lighter tint; *Thunia Bensonae*, very good; also *Anguloa Clowesi*, *Epidendrum vitellinum majus*, and *Huntleya albido-fulva*, an uncommon species. *Cypripedium hirsutissimum* was well coloured. Of *Masdevallia Schlimigii* there was a good example; also several good *Odontoglossums*, *O. Halli leucoglossum* and *O. maculatum* being two of the best. Award silver Banksian medal.

Messrs. Charlesworth and Co., Bradford, showed *Cattleya Mossia versicolor*, with the colouring of the lip, as seen in the best dark forms, running into the sepals and petals, distinct, but scarcely desirable. *Laelia grandis tenebrosa* was here represented by several plants in its best forms, each being well flowered; and *Oncidium macranthum* was shown in fine condition. A silver Banksian medal was awarded.

Mr. De Barri Crawshaw showed *Odontoglossums*, chiefly forms of *O. crispum*, each plant a picture of health. Note should be made of *Princess May*, with large blooms and beautifully fringed petals; *Pride of Rosefield*, an extra large

form, the spike bearing seven fine flowers. *O. citrosium* was here to be seen in a beautiful variety, viz., the *Rosefield*, having creamy yellow sepals and petals and a pale lilac lip, very distinct and choice in colour. *Laelia purpurata* *Crawshayana*, with the lip of a very dark purple and the sepals and petals of a rosy purple shade, was prominent; so was *Cattleya Mendeli*. Good forms of *Laelia purpurata* were shown, and in *Cattleya Mossia* Mrs. De Barri Crawshaw was to be seen a distinct variety. A most remarkable exhibit here was a grand form of *Oncidium Marshallianum* called *Crawshaw's Giant*, which well describes this plant, the spike bearing ten immense blooms, the colouring also being very deep; the name, however, is scarcely a desirable one. *Vanda suavis* and *V. tricolor* were included as cut spikes, each being excellent. Award silver Banksian medal.

Mr. Hamar Bass staged four fine plants of *Cattleya gigas* *Sanderi*, and to these a silver Banksian medal was also awarded.

Messrs. W. L. Lewis and Co. sent the following: *Bifrenaria vitellina*, *Cattleya Mendeli*, *Odontoglossum crispum* and *O. citrosium*, with *Cattleya Aclandiae*, *C. gigas*, and *C. Mossia*, as well as *Cypripedium Lawrenceanum* and *Odontoglossum vexillarium*. Award silver Banksian medal.

Mr. Chapman, gardener to Mr. R. J. Measures, sent an excellent exhibit of dried Orchid blooms mounted on paper, with the colours retained in a remarkable degree; so well were these specimens executed, that a silver Flora medal was awarded, and that most deservedly so. A few lines on the process adopted by Mr. Chapman would be welcome.

#### Floral Committee.

First-class certificates were granted to the following:—

**BENTINCKIA NICORARICA.**—A new Palm with a bold handsome leaf of large size and breadth, divided irregularly into several segments of varying width. It is quite distinct from any Palm at present grown. Shown by Messrs. F. Sander and Son, St. Albans.

**CYRTANTHUS OBLIQUUS.**—A robust and striking species, having a tall erect scape terminated by an umbel of drooping flowers which are a light brown or buff-yellow, shading to clear yellow, margined with light green. This also came from Messrs. Sander.

**BLANDEFORDIA AUREA.**—A very fine specimen of this was shown. The plant has long graceful grassy leaves, and it had more than a dozen flower-scapes which were 3 feet or more in height, each carrying a fine umbel of many drooping flowers. These are copper-yellow, shading to clear lemon-yellow at the tips of the segments. From Mr. Bain, gardener to Sir Trevor Lawrence, Burford Lodge.

Awards of merit were made to the following:—

**CARNATION CORUNNA.**—This is a yellow self of fine form, with a long pod that will not burst, the flower rich in colour. It is one of Mr. Martin Smith's raising, and was shown by Mr. Douglas, of Great Bookham.

**CALOCHORTUS LYONI.**—A notable addition to this graceful family. It has large flowers of a pale lilac colour when opening, but shading to almost white, with dark velvet brown blotches at the base. From Messrs. R. Wallace and Co., Colchester.

**IRIS ASIATICA.**—A magnificent bearded Iris with noble flowers as large again as those of *I. germanica*, borne high on stout stems, the standards rich blue, the falls of a violet-blue shade. This also came from Messrs. Wallace.

**BEGONIA B. R. DAVIS.**—A double-flowered kind of a deep self crimson colour. Shown by Mr. B. R. Davis, Yeovil.

**BEGONIA MONT BLANC.**—This is also double, and, as the name suggests, pure white. From Mr. B. R. Davis.

**BEGONIA LUCERNE.**—A distinct sort of novel and attractive colour, the outer petals soft apricot-yellow, shading to salmon on their edges, the

centre of the flower salmon-pink. From Mr. B. R. Davis.

**DELPHINIUM BEAUTY OF LANGPORT.**—This variety is a distinct break in a family where blue is quite the predominant hue. Its flowers are creamy white, the petals prettily tipped with pale sulphur-yellow. Shown by Messrs. Kelway and Son, Langport.

**PEONY LADY BERENFORD.**—A large-flowered variety of a soft blush-pink shade, delicate and beautiful. From Messrs. Kelway.

**PEONY DUKE OF EDINBURGH.**—The flowers of this kind are very double and of a deep rose colour. Also from Messrs. Kelway.

**PEONY SOLFATERRE.**—An elegant variety of soft colour, medium size and pretty shape, with outer guard petals which are white, the centre cushion of petals a pale cream colour. From Messrs. Barr and Son.

**STREPTOCARPUS DISTINCTION.**—This variety has fine flowers of a clear blue colour, feathered with violet-blue on the lower segments, and is a handsome kind. Shown by Messrs. J. Laing and Sons, Forest Hill.

**ROSE LAWRENCE ALLEN.**—A Hybrid Perpetual kind, having large, full flowers of a clear, soft pink shade, borne on strong, erect stems. Shown by Messrs. G. Cooling and Son, Bath.

**ROSE BLANCHE DE COUBERT.**—A variety of *R. rugosa* having double flowers, which are a little whiter than those of *Mme. G. Brouant*. From Messrs. G. Paul and Son, Cheshunt.

**INULA HOOKERI.**—A striking orange-flowered composite grown in all good collections of hardy flowers and too well known to need description. Also from Messrs. Paul and Son.

Mr. T. S. Ware, of Tottenham, received a silver gilt Banksian medal for a grand group of hardy flowers, in which Oriental Poppies, Irises, Lilies, *Canna Queen Charlotte* and *Brodiaea congesta*, with tall, robust scapes remarkably well grown, were prominent. Choice *Campanulas* in spreading, free-flowered masses, *Ramondia pyrenaica*, *Gypsophila prostrata* and *Carnations* were also noteworthy. Messrs. Kelway, of Langport, made a great display with *Peonies* in many fine double and single kinds, with *Delphiniums* and *Pyrethrums*. A silver Flora medal was awarded and a similar award was made to Messrs. Barr, who also showed hardy flowers in variety, *Peonies* predominating, the varieties very numerous, lovely and varied in colour. Irises, Day Lilies, *Anthericum* and *Dic-tamnus* were all fine in this group. Messrs. J. Veitch and Sons also made a great display with *Peonies*, and two noble spikes of *Eremurus robustus* in this group attracted much notice from visitors. *Streptocarpus* in variety were also shown, a silver Flora medal being awarded.

A very interesting group was that from Messrs. R. Wallace and Co., Colchester, containing some of the choicest gems among flowers of the season. In addition to *Calochortus Lyoni* (previously noted), *C. albus*, with about a dozen pure white flowers gracefully disposed on a strong stem; *C. pulchellus*, of a similar character, but rich yellow; and *C. amoenus*, deep rich pink, were charming, and are bound to grow in popularity, judging from the notice they attracted. Lilies were well represented, a fine form of *L. elegans* named *ornatus* being valuable for its earliness, the flowers orange red with black spots. Another handsome variety is incomparable, with flowers of a deep dark blood-red, shading to orange. *L. japonicum* *Colchesteri* was good, with pale sulphur-yellow flowers. Irises in many kinds were fine, especially *I. asiatica*, which received an award of merit. Some of the finest of the German varieties in cultivation figured prominently in this group, and we have never seen finer flowers of *I. Lorteti* than those shown here, of noble proportions and exquisite colour. Undoubtedly one of the most beautiful, it seems also one of the easiest to grow among the Cushion Irises. *Brodiaeas* were charming, also the best of them—*B. congesta*, *B. laxa* and *B. capitata* in blue and white. A silver Banksian medal was awarded. Mr. Prichard, of Christchurch, showed a charming group of hardy flowers, containing several fine things not shown

in other groups, as *Scabiosa caucasica*, the type and its pure white variety; *Tropeolum Leichtlini*, noted elsewhere; *Linaria dalmatica*, with long spikes of yellow flowers; *Salvia Hians*, a hardy kind, of a deep violet colour; *Orobanchis lathyroides*, having dense racemes of deep blue flowers; *Lathyrus rotundifolius*, an old, but lovely perennial pea; *Coronilla iberica*, rich yellow; *Betonica grandiflora*, handsome and well-grown spikes; and *Gillenia trifoliata*. A Banksian medal was awarded. Messrs. J. Laing and Sons staged a fine group of hardy flowers, in which Irises, Pæonies, and Pyrethrums were prominent; the improved kinds of *Streptocarpus* were also noticeable. A silver Banksian medal was awarded, and a similar award was given to Messrs. Cannell and Sons for a fine group of Cannas and Gloxinias in great variety. A charming group of old-fashioned, but still lovely garden Roses was shown by Messrs. Cooling, of Bath. *Rosa lutea* in single yellow and copper colour, *R. polyantha* and its large-flowered variety *R. rubrifolia*, with tinted leaves; *Lady Penzance*, one of the prettiest of the hybrid Sweet Briers; and many other sweet Roses that are in danger of being forgotten made a welcome reappearance in this group, to which a silver Banksian medal was awarded. Messrs. Paul and Son, of Cheshunt, received a similar award for a group of hardy flowers, in which dwarf Campanulas were pretty; alpine Pinks, attractive in variety; and single Roses, a prominent feature. *R. rugosa* in several forms was well shown, also *R. macropphylla*, with large single flowers of a deep pink. Mr. Mount, of Canterbury, showed cut Roses well, a box of Captain Hayward being conspicuous, whilst Gustave Piganeau, Princess of Wales, The Bride, and Edith Gifford were finely represented. A silver Banksian medal was awarded. Mr. Prince, of Oxford, had a similar award for cut Roses, a good lot of the variety Clara Watson being shown. Mr. Frank Cant, of Colchester, had a small exhibit of pretty garden Roses, and Messrs. W. Paul and Son showed their new Tea Rose Sylph in quantity. It is prettiest in the bud state. A new Tea Rose named Zephyr from the same firm looks promising for cutting, judging from the free-flowered clusters shown. It is of pale cream-yellow colour. Messrs. Veitch showed several hardy shrubs in flower, notably *Casalpinia japonica*, with long racemes of yellow flowers; *Hedysarum multijugum*, which has slender racemes of small pea shaped, magenta-red flowers. *Hypericum Moseianum* tricolor, attractive in variegation as well as in flower, and *Cornus brachypoda variegata*, *Lilium Ukeyuri* was prominent also. Some of the stronger stems carrying two fine flowers.

Mr. Louis de Smet, Leideberg, Ghent, showed a pretty silvery variegated *Abutilon* which is likely to become a popular foliage plant, being so distinct from any other kind, the variegation in the form of a broad white zone with the centre of the leaf grey-green. Small plants only were shown, and the committee wished to see it again. Mr. J. T. Bennett-Poë received a silver Banksian medal for a splendid specimen of *Carpenteria californica* growing in a tub. It was the picture of health, quite 7 feet high and had clusters of fine flowers all over. It attracted much notice. *Tropeolum Coolgardie*, which received an award of merit a short time back, was again shown by Mr. H. B. May in neat pyramidal plants profusely flowered. Mr. J. Douglas showed two good yellow Carnations in addition to the one previously noted, and Mr. T. Bones, of Heaton Garden, Cheshunt, showed a group of plants of a free-flowering sweet scented yellow self. Mr. C. Turner showed a pink flowered variety in the way of Miss Jolliffe named Mrs Greenfell, and Mr. Bliok, gardener to Mr. Martin Smith, staged a little group of a Malmaison variety called Lady Grimston, most distinct in colour, flaked with red on a lighter ground, but practically a self in effect. Mr. Campbell sent from The Willows, Windsor, a very formal trained specimen of *Bougainvillea glabra* named Campbelli, only a shade deeper in colour than the type. Cut trusses of seedling *Rhododendrons* fine in colour and of robust

character were shown by Mr. Anthony Waterer, also profuse sprays of the dark-flowered *Weigela Eva Rathke*.

#### Fruit Committee.

The exhibits before this committee were more numerous than usual, good Tomatoes and green vegetables being staged in quantity. The Strawberries of Messrs. Laxton were very fine and much admired.

Awards of merit were granted to the following:—

**MELON THE LADY.**—A small fruit, nicely netted with white flesh, the centre tinted with scarlet. A fruit of great promise, being rich, juicy and very solid. It is stated to set freely and crop well, and is just the fruit for a private garden. The committee requested it to be sent again when more ripe. From Mr. C. Thomas, the Royal Gardens, Frogmore.

**CARTER'S SPINACH.**—This was sent to Chiswick for trial by Messrs. Carter, of High Holborn, as the Carter Spinach, but the committee considered it to be the same as Carter's Long Standing and the award was made under this name. It was shown from the society's garden at Chiswick. It is a distinct type of Spinach with large thick green fle-ly leaves remaining good a long time, not running like ordinary forms. It will be a useful Spinach for light soils and summer use, and is quite hardy, having stood the winter well.

**TOMATO EXCELSIOR.**—A variety tried at Chiswick last season, receiving the award of three marks. The fruits shown were not first rate, and the committee wished to see better fruits before giving the higher award. It is to be regretted distinct names are not given, as this kind is very similar to the well-known Hathaway's Excelsior, having globular fruit smooth, in outline, solid and of good flavour. From Mr. J. Corlett, Mulgrave Castle Gardens, Whitby, Yorks.

Mr. Mortimer, of Farnham, staged a grand lot of Tomatoes of perfect colour and finish, also some twenty fruits of his new Cucumber Progress a very good looking fruit with little neck and a tremendous cropper; this variety was requested to be sent to Chiswick for trial next season, when the society intend trying Cucumbers. The most notable dishes of Tomatoes were Sutton's Perfection, Maincrop, Best of All and Al. Frogmore Seedling, a new fruit of last season, maintained its excellent form. Conqueror was very good, but more ribbed than usual. In all twenty four dishes were shown and a silver Knightian medal awarded.

Messrs. Laxton Bros., Bedford, staged a very fine lot of Strawberries in six varieties. Among them was a new fruit, a mid-season variety, very large, with firm flesh, deep red colour, and prominent seeds. It was named Monarch, and was awarded a first-class certificate, this to be withheld till the committee have tested the cropping qualities in the usual way. They requested Messrs. Laxton to send fruits to the next meeting. The other varieties comprised the recently certificated Leader, which was very fine and good in flavour, Sensation, a large variety, Royal Sovereign, remarkably fine, John Ruskin, and Noble. A bronze Knightian medal awarded.

Mr. Hindson, Gunnersbury House Gardens, Acton, received a cultural commendation for a very fine box of Lord Napier Nectarines, the fruits large and of very fine colour.

Mr. G. Wythes, Syon House Gardens, Brentford, staged a small collection of Peas, Beans, Turnips and Cauliflowers, open-air produce from plants raised under glass and planted out. Duke of Albany, Stratagem, Duke of York, Laxton's Gradus, and Veitch's Chelsea Gem Peas were very good. Dwarf Erfart and Walcheren Cauliflower, autumn-sown Syon House, Selected Mohawk French Beans, Veitch's Early Longpod Bean, very good, White Milan and Carter's Cardinal Turnip, Egyptian Beetroot and Potatoes were all first-rate. A bronze Knightian medal was awarded, and a similar award went to Mr. Pentney, Worton Hall Gardens, Isleworth, who staged a large collection of vegetables, having two lots of Tomatoes, Veitch's Selected Marrow, Ellam's Cabbage, Early

London Cauliflower, Giant King and Veitch's Ash-leaf Potatoes, very good, Hick's Cos Lettuce, Early Milan Turnip, Veitch's Selected and Chelsea Gem Peas, and other dishes.

Mr. Ward, Longford Castle Gardens, staged three nice boxes of Peas from plants raised in heat, receiving a cultural award, the varieties being Carter's Telegraph, very good, William 1st and Carter's Lightning. Mr. Crook, Forde Abbey Gardens, Chard, Somerset, sent a nice lot of Veitch's Chelsea Gem Peas, both on the haulm and gathered. A new Kale was sent by Messrs. Malden, Cardington, Beds, but it is out of season at this date. Mr. H. Staples, Belmont, Salisbury, sent some huge heads of Asparagus named Hative. Mr. G. Wythes sent Carter's Cardinal Turnip, a new variety, of a pink colour, solid and good; also the new White Milan Turnip, a pure white variety, and Veitch's Improved Early Longpod Broad Bean, the earliest variety of the longpods and very hardy. All these vegetables the committee requested to be sent to Chiswick for trial.

From the society's gardens was sent two varieties of Spinach, the one certificated above, and the Flanders; also some very fine fruits of Laxton's Royal Sovereign Strawberry. There were also shown green-fleshed Melons by Mr. Thomas, Frogmore; a large scarlet fleshed Melon from Mr. Spencer, Goodrich Court Gardens, Ross, Hereford; the new May Queen Strawberry, by Mr. Collis, Bollo Lane, Chiswick, and a few small exhibits of Potatoes.

Mr. Frank Cant gave a practical and most instructive lecture on "Rose Growing under Glass." Although Roses might be grown in almost any glass structure, according to his experience, that most suitable was a span roofed house running from north to south. A house 24 feet in length and 14 feet in width could have a centre bed 7 feet wide, a path 1½ feet wide, and then another border all round the house. It has often been said the Teas and H.P.'s could not be grown successfully in the same house, but he found they could in the form of arrangement he was suggesting if the Teas were confined to the centre bed and the H.P.'s to the outer bed. The Teas liked more sun, and by this arrangement shade when necessary could be given to the H.P.'s. Structural details of the house were enlarged upon, and removable lights suggested for structures in which the Roses were planted out. As regarding culture in pots, he remarked upon the importance of the plants having a season of preparation. It was impossible to pot up Roses in the autumn and flower them successfully the following spring; they must have a season of growth in pots first. The soil he found the best was good fibrous loam, cut and stacked with cow manure sandwiched between, allowing it to stand about six months. Judicious watering and ventilation were the secrets of success, and mildew, the worst of Rose pests under glass, was generally attributable to errors in this respect. The remedies advised for a bad attack are familiar, being treatment with sulphur. Green-fly, another pest to be reckoned with, could be kept in check by the syringe, but if it gained the upper hand at any time, fumigation must be resorted to, McDougall's sheets being the best possible thing for the purpose. As regards stimulants, they should never be applied till plants were established and in need of them. He preferred liquid manure from a cow yard; that from the stable was dangerous and needed careful dilution. Failing cow manure, there was nothing better than soot water obtained by steeping a bag of soot in the usual way.

**United Horticultural Benefit and Provident Society.**—The usual monthly meeting was held at the Caledonian Hotel on Monday evening last. Mr. Nathan Cole presided. Four new members were elected. It has been decided by the committee that the increase of sick pay from 10s. 6d. to 12s. and from 16s. to 18s. per week in the two classes respectively shall commence from

the half-year—July 8. The treasurer reported that he had invested £200 in West Bromwich 3 per cent. stock.

**Floral fete at Royal Botanic Society.**—Fortunately, fine weather favoured this now annual children's floral parade in the Regent's Park Gardens. There was a large attendance and a display of many tastefully decorated vehicles of all kinds, in some cases, however, the contrast of colour being none too happy. There were many exhibits in the large tent, as our list of awards will show.

**The People's Palace Horticultural Society.**—The summer exhibition of this society, originally announced for July 11 and two following days, will now be held on July 4, 5 and 6, in order to suit the convenience of their Royal Highnesses the Duke and Duchess of York, who will visit the show and be accompanied by the Duke of Fife, the president of the society; and in order that as many members of the society as possible may be in attendance, the visit will take place at 5 o'clock in the afternoon. On Saturday, the 8th inst., Mr. H. J. Jones, Ryceroft Nurseries, Lewisham, gave an address before the members of the society at the People's Palace, his subject being "A Chat about Chrysanthemums."

## NOTES OF THE WEEK.

**Pæonia Whitleyi.**—Mr. W. Macartney sends us from Clogher Park, Tyrone, fine flowers of this charming single Pæony and Oriental Poppies in bright and varied colours.

**Salvia Hians.**—This is the handsomest of the hardy Salvias, and a pretty species, but rarely seen now. A good bunch of it attracted some notice in Mr. Prichard's group of hardy flowers at the Drill Hall on Tuesday. Its flowers are large and showy, of a deep violet-blue colour.

**Aquilegia.**—I am sending a few flowers of some seedling Aquilegias raised here. The seed parent was Aquilegia glandulosa and they are all of that type, as you will see by the long spurs.—J. HUGGINS.

\* \* A pretty lot in varied colours, but these hybrids are now often raised in gardens.—Ed.

**Linaria dalmatica** was well shown by Mr. Prichard on Tuesday, the spikes of great length and crowded with large clear yellow, sweet-scented flowers. In the ground this plant is apt to become a nuisance, as it runs so freely. The best place for it is on the top of an old wall, and some of the fine spikes shown were cut from plants growing on a wall. It is one of the handsomest of the perennial kinds.

**Oncidium sphacelatum.**—The value of this Orchid for decoration was fully seen in a group of miscellaneous plants arranged for effect at the Whitsuntide exhibition at Southampton. Mr. W. Peel, gardener to Miss Todd, Sidford Lodge, Shirley, employed it largely and with good effect, associated with Palms, Ferns, a few Cattleyas, and other flowering plants. Many of the flower panicles were 5 feet long, arching beautifully.—E. M.

**Tropæolum Leichtlini.**—This, one of Herr Max Leichtlin's recent introductions, was admirably shown by Mr. M. Prichard at the Drill Hall on Tuesday. It is clearly related to *T. polyphyllum* and has a strong resemblance to that species at a casual glance, but the differences observable by close inspection are in its long, narrower leaflets; whilst the flowers are distinctly deeper in colour, being of quite an orange-yellow hue. The sprays shown were long and abundantly flowered.

**Brassia verrucosa.**—I enclose herewith a portion of a spike of *Brassia verrucosa* which, I am told by a good authority, is better bloomed than usual. The spike was one of six, of which this and another had each fourteen flowers, and the others twelve each. Thus grown it is, although old-fashioned and not showy, a very grace-

ful object. It is not *B. v. major*—at least I have another plant much larger in all its parts, but very shy about flowering. Kindly let me have your opinion on the enclosed.—G. P.M.

\* \* A very well-grown plant.—Ed.

**Eremurus robustus.**—With reference to M. Van Houtte's remarks on his *Eremurus robustus* and yours as to its being more robust than we have them in England, let me say that my plant (illustrated in THE GARDEN last year) has three spikes, measuring from base to tip of inflorescence 9 feet 3 inches, 8 feet 1 inch, and 7 feet 6 inches, the flowering portion of the tallest measuring 3 feet 8 inches. I am glad to say I have a nice lot of seedlings from last year's seed. We are dreadfully burnt up here, only 5 51 inches of rain since the beginning of the year.—F. PAGE-ROBERTS.

**Calochortus Lyoni.**—Without a doubt, as these become better known and their culture understood—which, by the way, is simple enough—they will have many admirers and be largely grown in gardens suited to them. The flowers, unique in form and lovely colour, have a grace and elegance peculiarly distinctive, and the family is growing in numbers and importance. The variety here named, and for which Messrs. R. Wallace and Co., of Colchester, received an award of merit on Tuesday, is a most noteworthy addition. It belongs to the Mariposa section and has fine, large flowers borne on tall, strong stems, in colour pale lilac, shading to almost white, with a rich velvet-brown blotch at the base of each petal.

**Iris asiatica.**—This noble Iris was shown in magnificent form by Messrs. R. Wallace and Co., of Colchester, at the Drill Hall on Tuesday, and it was deservedly given an award of merit. It is a native of Asia Minor and is clearly allied to *I. germanica*, but stands out conspicuous from all the *I. germanica* varieties by reason of its fine size and noble beauty. The flowers are immense, but admirably proportioned and borne on stems more than 3 feet in height. The standards are clear blue, the falls of unusual length, purplish blue around their edges, shading to a violet-blue in the centre. A good engraving that shows well the character of the flower was given in THE GARDEN of February 6, 1892, p. 121.

**Tufted Pansies.**—Mr. Forbes, of Hawick, sends us a charming selection of tufted Pansies, including many varieties of the Violetta type. We regret further needless classification of these as miniatures, which will bother many people. Except in one or two cases there is no difference in size, such kinds as George Muirhead, Sylvia and many more being as large as the best older Pansies. It is nice to see the great purity of colour of these delicate self-coloured kinds recognised even in nurseries where the florists' kinds had first place always. Among those we greatly admire are Gnome, yellow; Mrs. Primrose and George Muirhead, yellow with fine flowers; Jennie Turnbull, delicate blue; Picotee, blue, edged white; Blush Queen and Sweet Lavender.

**Magnolia Wataoni.**—A fine flower of this new species was shown by Mr. Hudson, of Gunnersbury, at the Drill Hall on Tuesday cut from a plant that has passed the winter in the open air quite unprotected. Its hardiness may therefore be taken as proved, and the tree planted with confidence as regards its future welfare. The flower is of the same character as that of *M. parviflora*, but larger. The flowers are ivory white in colour with a cushion of red filaments in the centre, large, showy and enduring. Apparently they come a little later than the flowers of *M. conspicua* and its varieties, which is fortunate, not only in prolonging the season of these noble flowering trees, but the beauty of their display is less likely to be marred by inclement weather. Although as yet we know little of these newer kinds, they promise well, and it is to be hoped that many will plant them.

**The weather in West Herts.**—On three days during the past week the temperature in the

shade was very high for so early in June, reaching respectively 73°, 78° and 80°. These were, however, the only readings which have been in any way exceptional as yet this month. At the present time the temperature of the ground at 2 feet deep stands at 62°, and at 1 foot deep at 63°. The latter reading is about 2° in excess of the average for June, and 8° higher than at the same period last year. About a tenth of an inch of rain fell on the night of the 11th, but the surface of the soil appeared as dry as ever at mid-day on the 12th. During the last six weeks only about half an inch of rain has fallen, and no rain water whatever has come through the light soil percolation gauge for a month, and none through the heavy soil gauge for more than a fortnight. On the 7th the sun was shining brightly for very nearly fourteen hours. I cut my first Hybrid Perpetual Rose from the open ground on the 9th inst., or ten days earlier than the average date for the previous nine years, and a fortnight earlier than last year.—E. M., *Berlhamsted*.

**A warning.**—Mr. J. B. Crace, of 38, Wigmore Street, writes under date June 5: "Allow me to warn your readers and advertisers against a cunning swindler. Wishing to obtain a good place for a former gardener of good character, I advertised on his behalf. Among inquiries in reply I had a personal call from a man who professed to be tenant-bailiff of a gentleman near Northampton, at whose request, so he said, he called to make personal inquiry about my gardener. This bailiff was a grazer on his own account and came to town once every week to attend the early cattle market. Now my gardener had temporary work some thirty miles from town, but the 'bailiff,' anxious to see the man for himself, decided that he would run down 'after the market was over' when next he came to town in a few days. He accordingly came again to me, ascertained that the gardener was not yet engaged, and his address, and departed, remarking that he thought he would be the very man. Well, my visitor carried out his promise next morning: took train into Surrey, found my gardener, and decided to engage him, but advised him to try the place for a week or two before moving his furniture. Just as he was going he remembered that his cash was short of what he would require to get back to Northampton, and borrowed £2 of the unlucky ex-gardener, who still awaits repayment."

## PUBLIC GARDENS.

**Lincoln's Inn Fields** are gradually being turned into a wilderness, and if the County Council intends to do nothing to check the destruction, the next best thing would be to asphalt the fields all over and chop down the trees. The children who swarm into this delightfully quiet, restful retreat ignore all appeals to keep off the Grass, so that it is now almost difficult to say where the paths end and the turf begins, so complete has the destruction become.

**Another public recreation ground.**—The owner of the land known as the Cross-bones Burial Ground has offered to sell it at a fair price if the land could be turned into a public recreation ground. The offer has been made to the St. Saviour's (Southwark) Board of Works, and a special committee has been appointed to consider the matter. The area of the land is 30,000 square feet, and the district in which it is situated much in want of an open space.

**Names of plants.**—*S. L.*—1, *Polemonium Richardsoni*; 2, *P. corulea*; 3, *P. corulea alba*.—*Mrs. S. Marshall.*—1, *Dianthus deltoides*; 2, *Rosa macrophylla*.—*H. Wate.*—*Oncidium flexuosum* and *Cattleya Mendeli*, a pale and pretty form.—*R. M. Laurie.*—White flower *Smilacina bifolia* and *Aceras anthropophora* (the Man Orchis).—*J. L. Mansell.*—*Hordeum jubatum*.—*C. B. B.*—1, *Allium Moly*; 2, *Delphinium nudicaule*.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ROSE GARDEN.

ROSE W. A. RICHARDSON.

THE popularity of this Rose was insured from the time of its first appearance at the shows, now many years back, when Rose lovers were astonished and charmed with its richly-coloured flowers. Now it is much grown, and, still remaining without a rival in its unique colour, has also proved one of the very best Roses for walls, fences, arches, or any situation suited to a Rose of vigorous climbing growth, whilst it is second to none in profuse and continuous blooming. Some years back complaints were made of its erratic behaviour, and we have had some experience of the same ourselves. Of two plants growing several yards apart, apparently under exactly the same conditions, one refused to grow at all, but just lived, whilst the other covered the entire space allotted to the two plants, and now annually hides the wall and its own leaves in a marvellous profusion of flowers. The first display is always a great one, but it does not exhaust the energies of the plant, as after a short rest it commences flowering again and blooms throughout the autumn. The flowers are also disposed to vary in colour, the blooms of some plants having their outer petals almost white, and only the rich apricot tint in the centre. These are disappointing, but, happily, they can be avoided, also the inexplicable failure of plants to grow. W. A. Richardson grows and flowers as well upon its own roots as on any stock; therefore propagation by cuttings from plants that bear the brightest and best flowers will give plants free from any defects of this sort. Plant own-root plants in light rich soil and they will soon show that they have abundant natural vigour, which is not increased, but often diminished, and the plant's life shortened by condemning it to grow on any other roots but its own. This Rose is quite as important as the best Dijon Teas, and surpasses these last in colour effect and lavish profusion of flowers.

**Tea Roses and frost.**—At Reigate Mr. Haywood has been able to preserve his dwarf Tea Roses admirably by adopting the simple process of earthing them up in the winter. Netting, artificial litter, Fern, cocoa fibre refuse, or similar materials are not such effective frost protectors as soil, especially if it be of a light nature. The effect of the earthing here, which was about 6 inches in height, was to protect every dwarf Tea Rose so well, that of very large numbers not one is missing, and all are making good, though late growth. The finest shoots, however, are seen on a few plants left growing amongst some bush Apple trees. Hybrid Perpetuals are all comparatively uninjured, and in many cases are showing prominent buds. A good rain is much needed, however, for all Roses.—D.

**Rose Belle Siebrecht.**—In the class of so-called Hybrid Teas are some very good garden Roses. This, one of the latest additions to that class, is already highly praised in America, and Messrs. Siebrecht and Wadley, of the Rose Hill Nurseries, New Rochelle, U.S.A., send us a very good coloured plate of it. The form of La France, one of its parents, is manifest in the shape of the flowers, which are of a deep rich pink and said to be very lasting. Doubtless it will soon be ex-

tensively tried in this country in the open air. Dean Hole was favourably impressed with it, and the leading pot and market Rose growers of America say much in its favour.

**The slaughter of the Roses.**—Though some districts escaped almost unhurt, others have suffered very heavy losses through the abnormally severe frosts of last February. The verdict of some of our largest growers in East Anglia is, "the whole of my standard Teas are dead, and dwarf Perpetuals on Manettis and Briers were so severely mauled and wounded by the frost as to ruin the spring trade." The latest tidings are that full half the Briers for stocks are dead, and on inquiring about famous Maréchal Niels in the open, "dead or dying," have been my only answers up to date. Another feature of the zero frosts is revealing itself daily. Roses pruned back to what seemed their lowest frozen branches are dying back still further. This is one of the most depressing phases of severe frost-bites in Roses or other plants and fruit trees, especially Peaches, Nectarines, and Apricots. Frost injuries run deeper and spread much further than appears at first.—D. T. F.

### ROSE NOTES.

CONSIDERING the havoc wrought among our Roses during the winter and the large quantity of wood destroyed, there is by no means a bad outlook at present. Upon walls and fences there is quite a show of flowers, Gloire de Dijon and all of the early varieties being very full. Banksians are better than for years past wherever their wood escaped the frost. My cut-back Hybrid Perpetuals are quite gay, and the season promises to be a good and early one. Certainly the date of the Crystal Palace N.R.S. exhibition will be suitable this year both for southern and northern growers. At the time of writing a gentle shower is falling, the first rain for six weeks or so, and our soil is parched up. It will be a great help to standard and half-standard stocks, many of which may yet be saved if the rain continues. As it is, there are more blanks than would have been the case if a shower had fallen early last month. Dwarf stocks are also sadly in need of a good rain. We have commenced budding upon standard Briers; this is necessary wherever a shoulder is ready, as they so soon go past that stage in which the bark lifts easily and clean. It is a good plan to lay out the number of steeks you mean to work with each variety and then bud upon the shoulders as they become sufficiently advanced. This is far better than waiting to take the bud right through, for not only do we get the shoulders budded at the most suitable stage, but we often have to procure our buds of choice varieties in more than one cutting. Close hand-picking is necessary still among the maggot and also with weevils and Rose beetles. The latter are more common than for many years so early in the season, and will soon spoil a large number of promising Rose buds. The heading of maiden dwarfs must be attended to if we want bushy plants, particularly for pot work in the coming autumn. Climbers do not need heading, nor do the dwarfier growing Teas and Noisettes, but to allow A. K. Williams, Alfred Colomb, and others of similar habit to grow up one shoot only is a mistake except where an early maiden bloom is wanted. Still keep the hoe going among maidens and all plants that are not mulched with manure. Surface stirring conserves the moisture and also does much towards keeping the plants clean and healthy.

Under glass young Roses are looking well, and may now have more air given. I was recently written to respecting the merits of growing Roses with ample ventilation or keeping the house quite closed day and night. It is more a matter of heat than ventilation. A little reason in ventilation will avoid mildew, while I am sure that too close an atmosphere with sudden changes of temperature will bring it on equally as soon as draughts from bad ventilation. Neither extreme should be practised. Some few years back I wrote a note

about the existence of two Roses under the name Souvenir d'Elise. For some time I have been aware that Duc de Magenta was about under the wrong name, but I am not now referring to this variety. There is one that we have purchased as Souvenir d'Elise and also as Souvenir d'Elise Vardon, and which turns out to be Pauline Labonté. Last winter I purchased a batch of Teas from France to refill a few of the blanks in my beds. They were guaranteed true to name, but I find Pauline Labonté once more sent me as Souvenir d'Elise Vardon. The true Souvenir d'Elise Vardon and Pauline Labonté are very widely apart in every respect, scarcely any two Roses more so. All of the other varieties are true, and probably the vendor considers this one correct also. I have heard of Souvenir d'Elise growing to enormous dimensions in Devonshire, and, from the description, have not the least doubt that Pauline Labonté is its correct name. Hybrid Sweet Briers are looking well, and I note that they are inquired for very closely. Both Lord and Lady Penzance are beautiful indeed, but are by no means the best growers here. R.

### THE MARKET GARDEN.

#### FIELD CULTURE OF VEGETABLES.

(Continued from page 406.)

#### ONIONS.

THE field culture of Onions is a matter of the highest importance to cultivators, as almost every year there is a dearth in the supply of full-grown harvested Onions to the Paris market so that the deficiencies have to be made up by large importations from Italy, the countries of the lower Danube, and even from Russia. And yet the sowing of a crop of Onions in spring to be gathered in autumn is one of the simplest operations and can be done almost in the same manner and as readily as sowing a crop of Oats.

The soil should be very well prepared and finely pulverised on the surface. Deep tillage is not advisable, as Onions bulb much better on a hard bottom. The seed should be sown at the close of February or during the first fortnight in March. If sown in drills from a seed-distributor the work of thinning out and weeding will be greatly facilitated. In soil of ordinary quality, seed of medium-sized varieties of Onions should be sown in drills 10 inches apart and the seedlings should be left 4 inches apart in thinning out. This would give about forty bulbs to the square yard.

Thinning out should be done early, so that the bulbs may attain their full development. If the thinnings are about as thick as a goose-quill and belong to an early variety, they may be put in the shade under a shed or even left on the field and turned over from time to time. Most of these thinnings will ripen and form small bulbs about the size of a marble, which are useful for pickling. The crop when once thinned out requires no further attention, except an occasional hoeing, until the bulbs are fit for gathering, which takes place when the leaves and stalks have withered. The bulbs are then pulled up and left on the ground for two or three days to dry, after which they are stored in a loft, being either thinly spread out on the floor or hung up in long "ropes" formed by interlacing the dried stems. Long keeping varieties should be grown in preference, as these enable the grower to choose his own time for selling when prices are most remunerative. Early kinds of Onions do not keep long enough for this purpose, and they are only suitable for cultivation in localities where Onions can be profitably sold in the young or fresh state.

The Oignon blanc rond dur d'Hollande, the Jaune paille des Vertus, and the Oignon de Douvres are the most suitable kinds for field culture and are long-keeping varieties. The second of these, a large and flat-shaped Onion, is the most commonly grown of all the coloured kinds in the neighbourhood of Paris. The other two, a white and a coppery yellow variety, are more globular in shape.

L'Oignon dur de Russe, which is largely imported in seasons when Onions are scarce in our markets, possesses valuable keeping qualities. The bulb is only of medium size, shaped like a short Pear or a Shallot, and is frequently divided into two parts, but keeps so well that it sometimes continues in pretty good condition up to the second spring after the time it was gathered.

L'Oignon rouge foncé and l'Oignon rouge sphérique are also good kinds for field culture, and, along with the Oignon rosé de bonne garde, may be mentioned here on account of their colour, which in some markets may be a recommendation for them.

In the neighbourhood of Paris it is estimated that the cultivation of an acre of Onions will cost £16, and that the crop will bring in £48. Were the profit only half as much, the field culture of Onions would be worth trying, and in the calculation of profits the grower should always bear in mind that the weight of a crop of Onions diminishes considerably as the bulbs become drier in the interval between the time of gathering and that of sending to market.

#### DANDELION.

Almost from time immemorial the wild Dandelion plants of the fields have been gathered and sent to the Paris market daily in quantities amounting to many thousand pounds weight.

A few years since the farmers at Saint Denis, Pierrefitte and the surrounding districts began to grow Dandelion in their fields, and this practice should be widely adopted. The crop is one which demands but little expense and labour, while the return from it is sufficiently remunerative. The seed is sown in well-prepared ground in drills which are from 1 foot to 16 inches apart. By the end of summer the surface of the soil is covered with the foliage and the plants form strong tufts, which should be earthed up before the ground becomes hardened by frost. All of this work can be done with a plough. During winter and the early part of spring the Dandelion plants, blanched in this way, furnish the material for an excellent salad and are quite as good, in fact, for this purpose as curled Chicory plants. Dandelion is also an excellent vegetable when boiled and should be more generally used in this way.

Several improved varieties of Dandelion have been obtained in the course of cultivation. The best of these is the full-centred one which forms very thick and well-furnished rosettes, which when well grown may attain a weight of 2½ pounds each. The broad-leaved and the curled-leaved varieties are also highly deserving of recommendation.

#### PEAS.

To a still greater extent than Asparagus and Green Kidney Beans have Peas become one of the articles of commerce that are sent from great distances, part of the Paris winter supply coming all the way from Algiers; consequently, our home growers cannot depend so much as formerly on the profits of their early or forced crops of Peas. They have a better chance of remuneration from late crops; for, at Paris, garden produce which comes into market after the regular season is over is sometimes more highly appreciated than early produce which anticipates the regular season.

There is also a large demand for green Peas at the factories for preserved vegetables, and for the supply of these the Peas must be sown on a large scale and gathered daily in order to have them as uniform as possible in size and in the proper degree of ripeness.

The dwarf varieties are undoubtedly the best for field culture, but they are generally less productive than the tall-growing kinds, and the pods are not so readily gathered. Moderately tall-growing kinds are, therefore, preferred for field culture. These, however, are not staked, but the plants, clinging to one another with their tendrils as they grow up, form a compact mass about 3 feet high, which can withstand wind and rain very well. In order to hasten the production and shorten the period of gathering the crop, the practice, in the neighbourhood of Paris, is to cut off the top of the main stem above the third or fourth joint at which flowers are produced. The pods then fill sooner and better, are fit for market earlier, and the gathering of the entire crop does not occupy so many days.

The varieties of moderately tall-growing Peas which are best adapted for field culture are Pois Prince Albert, Caractacus, and Michaux d'Hollande, all smooth, white-skinned kinds; Express and Pois serpette vert, smooth, green-skinned kinds; Shah de Perse and the Blanc and Vert ridés nains, the Peas of which are large and wrinkled when ripe.

Amongst the dwarf Peas, the Nain hâtif, Nain anglais, and Serpette nain vert are the hardiest and most productive.

Some green-seeded varieties are gathered when fully ripe and sold as dried Peas. Such are the Pois nain vert gros, Vert de Noyon, and Pois carré vert normand.

Amongst Peas, as amongst Kidney Beans, there are varieties with tender, edible pods, which yield a heavier crop than the ordinary kinds which are shelled. Although largely used in the eastern parts of France and in Switzerland, these edible-podded kinds of Peas are not much known throughout the greater part of the country. This is a pity, as the crop is more easily grown than the ordinary kinds, and demands much less hand labour. However, I would not recommend anyone to commence growing these edible-podded Peas before they have become a regular and established article of public consumption. In the case of any article of food the demand should always go before the supply, otherwise producers must run the risk of meeting with serious disappointments.

#### POTATOES.

There is no crop to which it is more difficult to apply a dividing line between the domain of field culture and the province of the market garden than Potatoes. This remark is applicable not only to those varieties which are grown for the manufacture of starch, for distillation, and for the feeding of cattle, but also to the kinds which are cultivated for table use. There are, in fact, few cultivators who do not grow a certain quantity of Potatoes for the use of the farm domestics, and very often a considerable portion of the ground that was broken up for other crops is devoted to the culture of Potatoes for the winter markets.

With this crop, as with others, the profit is not always in direct proportion to the weight of the yield, but varies under different circumstances of weather and local preferences. Generally speaking, the latest and most productive kinds are the least remunerative in proportion to the weight of the crop. The half-early kinds of fine quality pay better, and the very early varieties which are taken up before they are fully grown and sold fresh from the ground

command the highest prices of all. These, on the other hand, are the most risky to grow, as they must be taken up and sent to market by a certain date, so to say, and sometimes when the grower's attention is claimed by some other work more urgent.

Of these three modes of growing Potatoes, the most suitable for field culture is the late cropping one, by which the tubers are grown for the winter supply and can be used at home or sent to market, as may be necessary.

As numerous varieties are well adapted for field culture, the choice must be guided by considerations of soil and climate, and, in a great measure also, by local preferences. In one place round Potatoes are preferred to long ones; in another place the long ones are most in favour. The colour of the skin is also a subject on which the tastes of purchasers differ. At Paris the white kinds are generally preferred, but the red varieties are not despised, provided they have yellow flesh. In the eastern districts of France the red kinds with white flesh, and in the central districts the round purple-skinned kinds are fairly popular. For exporting to England, large-sized, round, or oblong, very mealy, white-fleshed kinds should be grown.

In France, the kinds which find the readiest sale are:—

1. CHAVE.—A yellow-skinned, yellow-fleshed, round variety, of good quality and very much grown.

2. LESQUIN OR SEGUIN.—A round, yellow-fleshed variety, raised in the department of the Nord, of very good quality and keeping well.

3. MAGNUM BONUM.—A long, yellow-skinned kind, very productive and keeping well, but the flesh is a little too white to be universally appreciated in France.

4. SAUCISSE.—An oblong, red-skinned variety, with deep yellow, firm flesh. This is the kind which is most extensively sold at Paris during the winter months.

5. QUARANTAINE VIOLETTE.—Another yellow-fleshed kind, of very superior quality and keeping for almost any length of time.

6. QUARANTAINE DE NOISY OR MARJOLIN TARDIVE.—A long, yellow-skinned, yellow-fleshed kind, of most excellent quality, the most highly esteemed and highest-priced variety of all. The Jaune de Brie is only a somewhat later sub-variety of this.

Amongst the winter varieties I must mention the Pousse-Debout and Vitelotte, the tubers of which are of elongated shape and firm-fleshed. Those of the first-named kind are smooth, while those of the other variety are notched. Both kinds are in great request at Paris.

The varieties which are grown for very early and mid-season crops are usually quite different from any of those which I have here enumerated. These, if the market prices are high enough, are taken up and sold before they are fully grown; but if it would not be profitable to do this, or should any other motive operate to prevent it, they are left to ripen, and are sold later on when they are fully grown.

The varieties which are suitable for this mode of culture are very numerous, but the following ten kinds are worthy of special mention:—

1. POMME DE TERRE VICTOR, the earliest kind of all, is an excellent variety of recent introduction. The tubers are flattened, long or shortly-oblong, with yellow skin and flesh, and very regular in shape and size. When grown in the fields the tubers may be taken up in the first or second week in June.

2. MARJOLIN HATIVE ("Quarantaine" of the growers around Paris).—A very early variety, the tubers of which are closely crowded together at the base of the stalks. They may be taken up for table use when even half grown. This variety and Victor are the best kinds of all for forcing.

3. **ROYALE OR ANGLAIS.**—Almost as early as the Marjolin when true to name, but spreads more at the root and is more productive. The tubers are very nice-looking and smooth and of excellent quality whether fully or imperfectly ripe.

4. **PRINCE DE GALLES.**—A more productive and later form of the preceding variety, the tubers being of larger size and sometimes resembling a Pear in shape, instead of exhibiting the usual almond-like form of the Royale.

5. **FEUILLE D'ORTIE.**—A yellow-skinned, long, very early variety, with small-sized stalks and white flowers. It is grown to some extent as an early crop and merits the favour which it receives by the fine appearance and rapid growth of the tubers.

6. **CAILLON BLANC OR LAPSTONE,** exceedingly handsome in shape, very smooth and of excellent quality, is grown extensively in the vicinity of Avignon, whence whole truck-loads of this variety are sent to Paris. It is distinguished by the tubers having velvety purplish "eyes" or buds, and by the peculiarity which they exhibit in the skin turning purplish instead of green when exposed to the action of light.

7. **JOSEPH RIGAUT.**—A handsome, long-shaped, very smooth kind, coming early into growth, but sometimes somewhat irregular in this respect. One of the good varieties of recent years.

8. **MARJOLIN TÊTARD.**—An excellent kind, quite distinct, with large, roundish or slightly oblong tubers, which are always flattened, of a bronzy yellow colour, and with yellow flesh of very superior quality and texture.

9. **QUARANTAINE PLATE.**—An exceedingly productive as well as a really early variety. Tubers very uniform in appearance and of a fine yellow colour both in skin and flesh. When it becomes better known this variety will certainly be one of the most extensively grown for market supply.

10. **KIDNEY.**—An early, red-skinned, and very handsome kind, coming quickly to maturity. Tubers very regular in shape, with a bright red skin and yellow flesh. This variety is to be recommended for localities where red-skinned Potatoes are preferred to any other kind, and such localities are tolerably often met with.

Besides the foregoing ten varieties, which are specially early ones, the Quarantaine de Noisy, the Rouge longue d'Hollande, and other winter-keeping kinds may also be grown to come in in autumn.

At the Halle market in Paris the price of different varieties of Potatoes often varies from 2s 6d. to 6s. 8d. per cwt., so that it will be seen how important it is to grow varieties which are in favour with the public.

2. *Vegetables which, requiring a good supply of moisture, are best adapted for cultivation in valleys where the soil is either naturally moist or can be readily watered or irrigated.*

I shall deal more briefly with the vegetables belonging to this section, as their range is more limited and the interest they possess is not so general from the circumstance that they require to be grown under special conditions.

#### ARTICHOKES.

Artichokes grow best of all in soil which is moist, but well drained, valley soils that are naturally of a somewhat peaty character being particularly well adapted for the culture of this vegetable. Paris is in a great measure supplied with Artichokes from the valley of the Oise, Anjou, and Brittany, the winter supplies coming from Provence, the Eastern Pyrenees, and Algeria.

In the south of France the variety which is chiefly cultivated is the Artichaut violet or gris de Provence, an early and productive kind, with more scales than bottom or receptacle. In the districts of Oise and Aisne, as also everywhere in the neighbourhood of Paris, hardly any kind is grown except the Artichaut Camus de Bretagne, which bears broad, roundish

heads, flattened on the top. Receptacle broad, but rather thin.

A well-made and well-managed plantation of Artichokes may during the three or four years for which it continues productive yield a clear annual profit, after all expenses are paid, of from £24 to £32 per acre.

#### BETROOT.

Beetroot for cattle feeding is grown in the field soil of ordinary flat districts or plains, and varieties for table use can undoubtedly be grown in the same kind of ground. As these last-named varieties, however, are more highly prized when tender and young, I have thought it better to include them, along with the other kitchen garden roots, among the vegetables which prefer a moister soil.

The crop of the earliest varieties of Beetroot comes in about three months from the time of sowing, and no variety occupies the ground for more than four or five months.

In their order of earliness the following kinds are to be recommended:—

1. **BETTERAVE NOIRE PLATE NATIVE D'EGYPTE** has a round, flattened bulb with red flesh, slightly barred with white. Leaves slight, with a green and purplish marble colouring. When sown in April the bulbs may be gathered for use in June.

2. **B. ROUGE NAIN.**—Root long and slender, very deeply coloured; leaves of a dark purplish tint. An excellent kind and keeps well.

3. **B. ECLIPSE.**—Root spherical and of a dark red colour. A productive and very good kind.

4. **B. ROUGE RONDE PRÉCOCE.**—Root large, round and slightly flattened. A very productive variety.

5. **B. ROUGE GROSSE.**—The longest rooted and most productive of the kitchen garden varieties. This is the kind of which the baked roots are so largely sold at the Halle market in Paris.

6. **B. CRAUDAINE OR ECORCE.**—The skin of this variety is black and full of cracks like the bark of a young tree; the flesh, of a deep red colour, is very tender or melting and very sugary in taste.

#### CARDOONS.

These can be grown almost exactly in the same way as Artichokes, and, when tied up and blanched on the spot where they are growing, furnish a winter vegetable which always commands a remunerative price in the markets.

The Cardon de Tours is the dwarfest variety of all and produces the most solid chards. It has, however, the drawback of being spiny.

The C. d'Espagne and C. Puy are not spiny, but they take up more space in the ground and do not yield such regularly solid chards as those of the preceding variety.

#### CARROTS.

All the market gardens in France are unable to produce Carrots enough for public consumption, and a considerable proportion of the market supply is grown in the fields.

The varieties of Carrots all require a mellow, moist, and well prepared soil; the long-rooted kinds, moreover, need to have the ground deeply dug and manured, and for this reason the half-long or stump-rooted kinds, which can be grown with shallower tillage, are generally preferred.

The old Carotte rouge longue is now being more and more superseded by the Carotte de Saint-Vallery, which is thicker and more conical in shape, very smooth, and of a fine deep red colour.

Amongst the half-long or stump-rooted kinds the varieties Chant-nay and Luc are very productive, and the Carotte Nantaise and the Demi-Comte de Guérande are exceedingly tender and of superior quality. The other varieties are purely market garden kinds. According to the size of the roots of the different kinds of Carrots which are grown in the fields,

an acre of ground may produce from 5 tons to 12 tons, representing a return in money of from nearly £10 to £16 sterling.

#### CELERIAC.

We cannot regard this as a plant that will succeed thoroughly well without artificial watering; nevertheless, outside of gardens it may be grown on a large scale in soil that is naturally moist. The seedlings should be planted out in May or June, taking advantage of the occurrence of showery weather, and after this they will make growth without any artificial watering. Celeriac is still a comparatively rare vegetable and pays very well when sent to market, as it keeps wonderfully well all through the winter, and is valuable at a time when the vegetable supply is rather limited in its variety.

The varieties of Celeriac which are most to be recommended for field culture are the Céleri-rave d'Erfurt and the Céleri-rave pomme, which are small-leaved kinds with bulbs of medium size, regular form, and excellent keeping qualities.

#### CHICORY.

Several kinds of Chicory may be grown in fields, notably the wild species for the production of "harbe-de-capucin," and the large-rooted or Brussels Chicory, the shoots of which, when blanched under a strong pressure, afford the vegetable that is called "Witloof" by the Belgians and "Endive" by the greengrocers and women-cooks of Paris. At Coupvray, M. Jules Bernard had, last winter, more than 25 acres of ground under Chicory, and was by no means dissatisfied with the returns from the crop.

The soil for Chicory is prepared and the seed is sown in the same way as for Sugar Beet or Carrots; the seedling plants, however, are not thinned out so severely. In September or October the roots are taken up and prepared most carefully in ways which are described in special treatises on the subject, but which it would take too long to mention here. Crops of the two kinds mentioned above are, as they are grown at present, very productive. Besides, at the end of the summer, in localities where the soil is moist enough, a crop of curled Endive or of Batavian Endive may be grown, which will come to perfection during the autumn and can be gathered at the beginning of winter. The plants of these Endives are tied up so that the heart may be blanched, and the crop is very profitable at a time when green vegetables have become scarce.

The varieties of Endive which are the most commonly grown in this way are Chicorée de Meaux, C. de Ruffec and C. de Rouen, and, most of all, the Scarole ronde or Batavian Endive.

The Chicorée reine d'Iliver and the Scarole en cornet are hardier than any other varieties, and constantly withstand the winter in the open ground about Paris.

#### CABBAGES.

The field culture of heading varieties of Cabbage is always attended with a certain amount of risk, as the occurrence of a period of unusually dry weather, with its ordinary consequences of a check to vegetation and an increase in the numbers of the Haltica, or black flea, may place the crop in jeopardy. On the other hand, under favourable circumstances, few vegetables furnish such an abundant and profitable crop as Cabbages.

The soils which are most particularly suitable for the culture of Cabbages are those which are naturally moist or even slightly sour. Meadow land and land which has been recently cleared of trees or shrubs always yields the finest Cab-

bagas. Wherever a system of irrigation is of necessity established the water of which is charged with fertilising matters, Cabbages are the most suitable plants for utilising the superabundance of very nutrimental plant food. So it is that in the neighbourhood of Paris Cabbage growing is most extensively and most profitably carried on in the plain of Gennevilliers, which is irrigated with sewage water.

Amongst Cabbages, as amongst Potatoes, there are some varieties adapted for furnishing a winter supply, and others which, coming in earlier and not keeping for any length of time, must be cut for use as soon as the heart is fully developed. These last-mentioned kinds do not occupy the ground so long as the others, but a good market price for them is more uncertain.

Of the early kinds I may mention Chou Express, Chou hâtif d'Etampes, York, and Oxheart, all of which are too well known to need any description here. A variety which, on the other hand, is almost unknown in France is the Chou Jersey Wakefield, which originated in America, and appears to me to be one of the best early kinds for field culture in plains. It is a short, conical-headed Cabbage of a glaucous green colour, heating quickly and firmly and attaining a weight of from 2 lbs. to over 4 lbs. It withstands hot, dry weather in quite a remarkable manner.

Of the good late or mid-season kinds which yield heavily and keep well through the winter, or may be used in the manufacture of sauerkraut or as a preserved dried vegetable, the very best are the Chou Quintal or Chou d'Alsace, which is of large size, flat, and very firm; the Chou Quintal d'Auvergne, which is still bulkier and rounder in shape; the Chou de Brunswick, which, from the shortness of its stem, has been so appropriately named Chou Tabouret; the Choux de Winnigstadt and de Poméranie, which have conical-shaped heads, and the large-sized kinds, Choux de Milan, Milan des Vertus, and Pontoise de Norwège, the last-named of which can be left in the ground during the winter, so that the crop may be cut after all the other kinds have been cleared off.

Red varieties of Cabbage can also be equally well grown in fields, and these are often a more remunerative crop than the white kinds. Lastly, Swedish Turnips and Kohlrabi may be very advantageously grown in fields, especially if the seed is sown late, so that the plants may be somewhat checked in growth before attaining their full development. This has the effect of improving the quality very much, and if the plants have been left pretty thick in the ground, the total weight of the crop will be little, if anything, under the average.

#### GOURDS OR PUMPKINS.

There are very few districts in France where one may not see here and there a few plants of Pumpkins grown in the fields. In Touraine they grow the large Pumpkin (Citronille) for feeding cattle, and in the neighbourhood of Paris it is in the fields that Pumpkins are most commonly grown. This practice should become more widely extended, due regard, of course, being had for local usages and preferences.

Almost all the kinds of Gourds, especially those of medium size, may be grown without any artificial watering, and the number of kinds as well as of varieties of form is very considerable. The Vegetable Marrow is fit for table use when one-fourth or one-third grown, and the plant continues in bearing for two months together.

The curiously-shaped Custard Marrows and the Turk's-cap or Timban Gourds are much in request, not only for table use, but also for

decking the windows of restaurants, while slices of the smaller field Pumpkins find a ready sale in the markets.

#### TURNIPS.

Catch-crop cultivation, for which Turnips are so well adapted, may be employed to furnish varieties for table use as well as those kinds that are grown for feeding cattle. All that is necessary is to sow in the best prepared ground seed of early varieties which are in request in the markets of the locality. In this respect, as in many other cases, it is necessary to take into serious consideration the tastes and preferences of the locality, however arbitrary these may be. It is hard to say why the people of Paris do not like yellow Turnips, or why, in other places, long ones do not please the popular taste. Such prejudices as these are assuredly devoid of any justification, but when we have to deal with the public as our customers, we must conform to their notions and only endeavour gradually and skilfully to persuade them to adopt new ideas and use new kinds of vegetables, the more so as there is no lack of good kitchen garden varieties of Turnips, whether anyone wants them long, round, flat, white, red, yellow, or even black.

Of late years the farmers around Paris have begun to sow on their stubbles the small Navet de Milan, and they have found this a very profitable crop. The white and red early flat varieties Blanc rond de Jersey, Boule d'Or, and Jaune de Montmagny, and even the long tender kinds, such as the Navets des Vertus pointu and marteau, may be grown in this way for the winter markets, which are the most profitable and the least exacting in requiring produce to be sent in by a certain date.

#### LEEKs.

It is always a matter of surprise to me that Leeks are so little grown in places where cultivation is in other respects in an advanced state; while in some provinces at a distance from Paris one frequently comes across fields of Leeks or rows of Leeks growing interposed amongst other crops. And yet it is a vegetable that is always appreciated and its price is seldom lowered in our markets. Moreover, it possesses the very valuable quality of keeping well in the ground in winter, so that it can be taken up for sale when and as required. It would be a very exceptionally severe winter that would cause the hardy Leeks of the north of France to suffer from the cold. After a few months of culture they yield a crop more or less heavy, much heavier, in fact, and more profitable than many would suppose at first sight. When the ground has been well prepared and manured a large-sized variety of Leek, such as the Carentan, is capable of yielding, without any artificial watering or special attention, from 20 tons to 24 tons per acre, the plants being grown eight to twenty-five to the yard, according to the method practised. The clear profit per acre may easily range from £32 to £48 sterling.

The Poireau gros court de Rouen and the P. monstrueux de Carentan are very well adapted for field culture. Showing but little over ground they withstand frosty weather well. The Poireau long d'hiver de Paris may be planted more closely together. This variety commands the highest price at the Halle in Paris. Local considerations must always influence the cultivator in deciding which variety will be the best for him to grow.

#### SPINACH-BEET OR CHARDS.

This vegetable is not so much grown in France as it might be. Except in the vicinity of Lyons and in Provence, where it is uni-

versally grown, one very rarely meets with it in cultivation. And yet it would form a useful addition to the list of late-season kitchen garden products, which are not very numerous.

Chards are grown in exactly the same manner as ordinary Beetroot in any kind of good, free soil. Everyone knows the Poirée blonde commune, the leaves of which are eaten entire cooked like the leaves of Orache and Spinach. The leaves of the Chards may be used in the same way, but these have besides a broad fleshy stalk, the flavour of which is very peculiar and very agreeable, resembling that of the Cardoon combined with a delicate and slightly acidulous taste. The best variety is the Poirée blonde de Lyon, the stalk or chard of which is white. Until this vegetable, however, becomes better known and more generally in demand, it would be rash to undertake its cultivation (or anything like an extensive scale.

#### SALSIFY AND SCORZONERA.

Like the kitchen garden varieties of Carrots, these roots can be easily and very profitably cultivated in the fields. All that is required is to sow the seed in spring in well-dug ground in drills from 8 inches to 10 inches apart, and the subsequent treatment is limited to a few hoeings, in the course of which the young plants are thinned out if they have come up too thickly. In autumn the roots are lifted as required and sent to market in bundles of about 5 lb. weight each. Salsify roots must of necessity be all lifted by the end of the first year, as after this the plants, if left in the ground, will run to seed and become unfit for table use. Scorzonera roots may remain in the ground for two years and flower without losing their culinary value to any great extent.

In concluding this long review, let it be very clearly understood that it by no means expresses any intention of mine to advise farmers to adopt or even to attempt the cultivation of all the vegetables which I have here enumerated. If every farmer set himself mainly to grow vegetables for market, the market gardeners would have to give up business, which would be a great pity, since the division of labour is generally at the bottom of all solid progress. I must say that my purpose was to afford information, not advice. At the present day, more than ever, it is necessary to confine oneself to such branches of industry as one is able to carry out well, and which one's circumstances will permit of being undertaken with profit. Now, there are few farms on which the conditions of soil, climate, and proximity to or distance from a market would not enable the farmer to grow some kind of kitchen garden vegetable with profit. This branch of culture would bear to the general farm crops much the same relation of an accessory character as poultry-raising or the breeding of various animals, &c. It would certainly be of minor importance to the main products of the fields, yet at the same time would be no insignificant, but sometimes a very profitable, addition to them. In this respect the cultivation of kitchen garden vegetables in fields recommends itself to the attention of the farmer, and also because it forms a good school for educating the farm labourers.

Gardening, it has often been said, is agriculture in its highest form of expression, and it is a good model for the practice of field culture to have before one's eyes a few pieces of ground tilled and manured to the maximum degree, and largely repaying with their produce the outlay which such tillage has involved. This forms a school of advanced agriculture—of agriculture with enlarged operations and bringing in large returns.

FLOWER GARDEN.

GAILLARDIAS AND GYPSOPHILA.

Two charming and popular garden flowers are here illustrated arranged in a simple and pleasing way, which shows the characteristic beauty of each. The effect is as light and graceful as that of the most careful and intricate arrangements such as one sometimes sees, perfect examples of detailed elaboration, but which neither appeal to the eye nor give that sense of satisfaction which comes from such an arrangement as this of familiar flowers artistically blended, yet still showing their natural pose and form.

THREE KENTISH GARDENS.

ALTHOUGH Kent is called the garden of England, we are not (at any rate in the eastern part of it) famous for our private gardens. Those attached

between bedding out and herbaceous plants. The garden which surrounds Swinford Manor House is a compromise between the two systems: the ground in which the quaint old house stands is level. There is a good-sized lawn fronting the house in which beds are cut in the Grass, and filled both in spring and summer with either annual or half-hardy plants. At the time of my visit they were filled with Forget-me-not, rising out of which were fine yellow Tulips. Around this lawn and in beds under the windows of the house are to be found many herbaceous plants, of which there is a good collection, while in the garden at the back of the house some of the choicer varieties are cultivated. When the Forget-me-nots, Primroses, and other spring plants, of which there are a great number, are removed, their place is occupied by Geraniums, Begonias, Cannas, and other summer flowering plants. Roses occupy a prominent position. At the time of my visit, although the winter had been very severe, the Tea Roses were making vigorous growth. The weather which we have had lately has been of a very exceptional character, and I should almost have fancied the drought,

glaring character, and the plants which everywhere sprang up between them have some of them acquired considerable size and are evidently making their way in their new quarters. The garden stands in an elevated position, and although the severe winter had made some gaps, they were not so numerous as in some gardens I have seen on a lower level. A fine Judas tree has been killed, also many plants of Cistus, a class which seems everywhere to have suffered, while other things have stood remarkably well. *Romneya Coulteri* was in good condition, and Lilies, which have not generally done well here, seemed to be in a very flourishing condition. As everyone who grows herbaceous plants knows, the end of May is about as difficult a time for them as any; the early spring beauties—the *Gentians*, *Aubrietias*, *Anemones*, *Primulas*, *Scillas*, &c., are past, and *Irises*, *Paeonies*, *Aquilegias* and *Delphiniums* are not yet in. *Arenaria grandiflora* was in good flower and a striking species it is; *Ranunculus amplexicaulis* was here in quantity, and its beautiful white flowers make it very attractive. Then there was the showy *Orobanchaceae*, much superior to the ordinary variety, and a good clump of *Sparaxis*. I cannot understand why this genus should be so much more amenable to culture, whether in the open ground or in pots, than the very closely allied *Ixias*. The former I can grow on in pots from year to year, but the latter (although I grow imported bulbs) will do nothing the second season and very often but little the first. *Sisyrinchium grandiflorum* was also in quantity, and there was as well a very highly-coloured *Dodecatheon splendens*, a brilliant form of the American Cowslip, deep crimson in colour, with a yellow rim. This is one of the few places where the *Eremurus* has been successfully cultivated. Last year a plant of *Eremurus robustus* attained the height of 13 feet. This plant is again sending up a flower-stem, while *Eremurus himalaicus*, the most beautiful of them, is also showing strongly for flower. *Verbascum olympicum* was to be seen in various places not yet in flower, but it seeds itself freely all over the garden. This is generally considered a biennial, but I have now a plant of it making growth in its fourth year, but (whether this is the consequence of it I do not know) it never seeds at all. Its behaviour, to say the least of it, is eccentric.

MR. R. FREMLIN'S, WATERINGBURY.

This garden is entirely different from the other two which I have previously attempted to describe; it was to it that two years ago I made a pilgrimage for the purpose of seeing that fine Bellflower, *Ostrowskia magnifica*, and which I attempted to describe in THE GARDEN. It withstood well the frost of last winter, and although not now in flower, is making good growth and will, I have no doubt, in due time be a grand sight. The garden is extensive, on beautifully undulating ground, and is occupied mainly with flowering shrubs and herbaceous plants. Although standing high up, it did not escape the severe frosts of last winter; a large *Wistaria* was killed outright, and the large Rose tree, which I described as clambering up over an Apple tree, has also perished. Flowering shrubs are much valued here, and some of the best new varieties of Lilac, single and double, light and dark, were in bloom. Hardy Azaleas also contributed much to the gay appearance of the place, and large masses of herbaceous plants some feet in length, such as *Saxifraga Wallacei*, were very pleasing, while along the border where the *Ostrowskia* flourishes are collected a number of beautiful herbaceous things conspicuous either for their beauty or rarity. Probably the rarest of these is that beautiful New Zealand composite *Celmisia spectabilis*: the plant does not grow above 6 inches high, and the flowers are large, about 2½ inches across, white, with a golden centre. Like many of the New Zealand plants, it stands on the borderland between hardiness and half-hardiness, and I question its power, except in some favoured localities, to stand the severe cold of our winters. A mass of *Cypripedium spectabile* was pushing up strongly,

Gaillardias and Gypsophila in a vase.

to most of our large houses always were of a rather common-place character, and the old bedding-out system still survives in most of them. There are a few bright spots, such as Mr. Hammond's, of St. Alban's Court, though, I fear, that too is not what it once was. In Mid-Kent, however, I think the case is different, and I have lately visited one garden in my own neighbourhood and two near Maidstone, each of them differing in character, and all presenting objects of interest, and a brief notice of them may not be unacceptable to your readers.

"THE GARDEN THAT I LOVE."

I suppose that most of your readers know the charming little book in which under this title Mr. Alfred Austin has described his garden. Mr. Austin is a poet, and therefore thinks that a poet's garden should always be bright and full of colour, and so he has compromised the matter

which has now lasted for many weeks, would have injured them, but they seem to have withstood it remarkably well if I may judge from my own plants.

ST. HELEN'S, EAST FARLEIGH, MAIDSTONE.

This is a garden of herbaceous and alpine plants and there is no bedding-out either for spring or summer. Two years ago I visited and described in THE GARDEN what struck me then to be the most remarkable things contained in it. It was at a somewhat later period than my present visit, and consequently many of the plants I then mentioned were not as yet in bloom, but there was much of great interest, although, perhaps, the lateness of the season deprived me of the pleasure of seeing the *Irises*, of which Mr. Carrington Ley has an extensive collection, and since I was last there a good deal of the newness of the rock garden has worn off. The stones have become of a less

and, in fact, everything about the place showed marks of vigour—groups of Iris, large double and single Paeonies were noticeable. Lilies were also growing strongly, and will no doubt in due time delight those to whom this beautiful tribe is a never ceasing source of pleasure. Such is a brief notice of these three gardens, each so different, and yet each having its special claim on those who take pleasure, I will not say in old-fashioned flowers, but in permanent occupants of our garden borders, for it is remarkable how small a percentage of the plants we cherish in our herbaceous borders can be classed amongst these former. We have ransacked the world in order to gather together the most beautiful plants of the cold or temperate regions, and these are the plants which we most cherish. I do not think that we are likely to go into ecstasies over the old Columbines when we have those lovely kinds, hybrids from *Aquilegia chrysantha*, *A. coerulea*, and *A. Skinneri*, with their long spurs and varied colouring with which now without any trouble our gardens can be well stocked, as they are most free in seeding and are constantly visited by bees, moths, &c., so that we never know what colours we are likely to get. There is one other garden in the neighbourhood of East Farleigh where I am told herbaceous plants are in great favour, but which I have not had an opportunity of visiting. I hope to go some time in the summer, and may, perhaps, be able to say something concerning it in the pages of THE GARDEN. I must also note a plant which I do not often see—*Lithospermum canescens*, not of the intense blue to which we are accustomed in some of the other species of this genus, such as *prostratum* and *Angastoni*, but of a bright yellow: it was only just beginning to show its colour. DELTA.

#### NOTES ON HARDY PLANTS.

*Spiræa arguta*.—This is now getting popular in gardens, and well does it deserve the honour of a conspicuous place. It is one of those subjects that cannot be over-praised. It chanced that one of perhaps the oldest specimens of the kind is here, and as it had grown too large for its place, was freely cut back in the autumn of 1893, and the bush was both improved in shape and the flowers have been more numerous and in bolder pose than ever this spring. So striking was the bush at one time, that one could not refrain from going to it many times a day, when one's eyes were dazzled by its pure whiteness, lines of arching twigs, touched off at their points with thin black points, resembling tasteful appendages of thread or cord. About a well-grown and flowered specimen there is both symmetry and elegance. The stature may be anything from 2 feet to 5 feet.

*Andromeda fastigiata*.—For seven weeks this has been white all over with its hundreds of wax-like little bells. It has the reputation of being hard to cultivate, but it is not so if granted two requirements, which are not hard in most cases, viz., fairly pure air and a position where not only its peaty soil is kept fairly moist, but the atmosphere, for instance, in a slightly shaded place and among numbers of other shrubs, which help by leaf evaporation to keep the air soft, like that of a wood bottom on a hot, dry day. This seems essential from the peculiar and scale-like character of its leaves, which hardly look like leaves at all. Unless these are well sustained by moisture both from within (their roots) and without, the leaf-enveloped stems soon go soft and are restored to plumpness with difficulty. I find for pot specimens that cocoa-nut fibre or damp peat answers admirably as a plunging material. With regard to pure air, I am not favoured with this by any means, but it is not very bad relatively to that of some districts near big towns, being on the west side of Leeds, the prevailing winds bring almost pure air from the distant hills.

A pleasing blend of flowers, which to my mind suggest either a bedding idea or harmonious groups, occurred here in May, and up to the

present has grown more bright or effective, and, owing to the long endurance of the flowers and also the succession, bids fair to last some time longer. The white flowers are the feathery panicles of *Saxifraga pyramidalis* and *S. cotyledon*, and the pale blue or mauve, the spikes of corresponding stature of *Nepeta Mussini*. The *Saxifragas* are in a good-sized mass of 100 plumes or more, the *Nepeta* plants are interspersed somewhat thinly, and then finished by thickly flanking the white. Both these are perfectly hardy and will stand for years in the same place. Both also enjoy a somewhat sunny and dry position.

**Choice early Saxifragas.**—A capital set of eighteen or a score comprise the under named, as tested for reliable hardiness and free-flowering after an exceptional winter like 1894-95: *Kotschyi*, *Bursleriana*, *B. speciosa*, *Bursleriana* seedlings in variety (white, cream to yellow), *Boydi alba*, *Boydi* (yellow), *oppositifolia* in three or four varieties, *sardica*, *marginata*, *Malyi*, *luteo-viridis*, *Rudolphiana*, *sancta*, *Cymbalaria* (annual), *biflora*, and *peltata* (before the leaves, a very large species).

*Aletris farinosa*.—I was surprised to find this had not only survived the winter on an open rockery (the base), but to see it sending up a spike. The flower-spike, however, has failed to develop beyond 3 inches, owing, I believe, to the very hot position during early May where a great amount of heat is trapped, which by other plants as well as by the *Aletris* has been resented. Still the plant is growing, and that is the chief point of this note—its hardiness against 30° of frost.

*Gentiana ornata*.—This is another instance of a pleasant surprise. The one plant I left out on an exposed situation without any protection whatever is now a far more sturdy specimen than any of the set stood all winter in pots and in a cold frame. It is, therefore clear to my mind that whatever may have been the cause or causes of the death in past years of this Indian species, it cannot have been cold merely. Possibly it may have been cold and wet with sudden changes in winter; if so, we can in a measure guard our plants against the wet. The cold, however, we cannot well escape, and it is well to know in this case that cold alone has not been the death of the plant.

*Courisia coccinea*.—I saw this promising well for flower in the rock gardens of Mr. Alfred Sykes, The Tower, Cookridge, the other day. It was being grown in a flat position, and as I observed where the plant had run to the side of a cropping mass of rock, and consequently got a little shade, the flower-spikes were more numerous than on the more exposed portions of the plant.

Woodville, Kirkstall.

J. Wood.

#### FLOWER GARDEN NOTES.

**SWEET PEAS.**—These flowers entered rather largely last year into the summer decorative work required about the mansion, and they were so satisfactory as to warrant an increased supply for the present season. For covering a long stretch of wirework they were sown in boxes in February and had the shelter of a cold frame during the exceptionally severe weather experienced throughout that month. The boxes were transferred to their summer quarters about the middle of May, and the Peas as they progressed in growth have been lightly secured to the wirework by lengths of twine. Sweet Peas also this year take the place of some tall plants of Japanese Honeysuckle that have hitherto been used for clothing iron pillars, and which were so crippled by the severe winter as to be practically useless for the present season. For this latter work the Peas were sown thinly in pans, 1 foot square by the same in depth; they are now just coming into flower and will look very well indeed. Where roots are confined in pans or boxes very liberal doses of liquid manure must be given as soon as the plants commence to flower to keep the growth moving rapidly, and all decayed flowers must be promptly removed. I

have found Emily Henderson and Firefly two capital sorts for this particular work. Those who provided a deep tilth and a liberal supply of manure for those outdoor borders where Sweet Peas were sown will be the most likely to secure a good and continuous display of flower if the weather keeps hot and dry. A heavy surface mulching and a good soaking of water is, of course, very beneficial, but in the majority of places outdoor flowers in any shape or form cannot often receive such attention at a busy time of the year.

**FLOWERS FOR PRESENT CUTTING.**—The season of *Pyrethrums*, *Aquilegias*, *Paeonies*, hardy *Azaleas*, &c., is getting a little over, and one has to hunt about to find other things to help out with the *Roses*, and the demand for cut flowers is on so extensive a scale, that it is not always an easy matter to meet all requirements continuously right away through the season. Nearly all hardy flowers, however, fortunately adapt themselves to vase work, and that being so, it is most important to take note of any weak point in the succession available, and to see the particular varieties required in quantity at such a time are strengthened by increased propagation when the time for this is at hand. In shrubs, *Weigelas* in variety have been useful up to the present time, and their place is now filled by the large-flowered *Syringa*, *Philadelphus grandiflorus* and the single and double forms of *Deutzia scabra*. Whilst on the subject of white flowers I may note that a good outdoor breadth of *Spiræa japonica* is always very useful, and the season may be considerably extended by having two such breadths respectively on south and north borders. I noted some time back the planting of *Foxgloves* in quantity among brakes of small seedling *Rhododendrons*, and from the present time (June 5) onwards for several weeks their spikes will be very acceptable. As in the case of the *Spiræas*, the season can be considerably extended by planting in different positions. A batch of *Delphiniums* planted in a similar site is supplying just now the various shades of blue. A lot of *Iris germanica* are still to be had from old established clumps, and a batch of the smaller Spanish *Iris* planted early last winter is coming out fast. Plenty of sun and the dry time has been answerable for an early development of flower on the varieties of *Phlox suffruticosa* and the large heads will soon be out. This is, however, one of the flowers I am always very loth to cut unless we are hard pressed, as given a considerable number of plants together, the magnificent heads have a very fine effect, and once shorn of their bloom the plants have a very formal, stick-like appearance. Another plant showing flower somewhat earlier than usual is the *Pentstemon*, long spikes of which are very acceptable for tall vases. Poppies increase in favour with each succeeding year for light and graceful vase work, and we have this year considerably increased the size of the breadth sown. The *Shirley* and *pavoninum* (annual) and the varieties of *nudicaule* (perennial) are the favourites. Very charming dinner table arrangements can be made with these Poppies associated with a choice assortment of ornamental Grasses culled from a neighbouring meadow. Looking through a large breadth of Pinks in several varieties that were planted specially for cutting, I see that Ernest Ladham's is considerably later than any other sort we have. This will just hit the season nicely between the bulk of the Pinks and the earliest border Carnations. Scattered about here and there among the Pinks are a few nice clumps of the Sea Lavender (*Statice latifolia*), which answers for autumn the purpose served by *Gypsophila* through the summer months. Our plants of this *Statice* were very sickly at the end of 1893, so I shifted them from the place they then occupied, cut them up, and replanted (doing them thoroughly well) on the border that was presently to be filled up with Pinks. The growth made in 1894 was very weak, and we had none of the handsome panicles of flowers, but this year the clumps are coming away strong and well. Writing of two plants whose flowers from July until the end of the year

are used as a substitute for foliage reminds one that for the supply of foliage on a large scale for a similar purpose there is nothing to equal the common Asparagus. It is not advisable to be continually cutting from permanent beds that are in use for culinary purposes, so to secure lengths of foliage for the flower basket, a little seed can be sown thinly in drills at 2 feet apart in some corner of a slip garden any time early in spring. It will naturally be of little use the first season, but can always be relied on afterwards to furnish a bountiful supply. It is not in every garden that the well-known seaside shrub that seems to revel in the salt spray (*Tamarix gallica*) does thoroughly well; where, however, this is the case, long and elegant sprays of foliage can be obtained in quantity from old-established plants.

**DAHLIAS.**—Where earwigs are troublesome, they are bound to muster in strength after the prolonged spell of hot, dry weather, and it will be found advisable to put the stakes to the Dahlias at once even if the plants are rather small, and to place inverted flower-pots containing a little dry hay on the top of the stakes with a view to entrap the enemy before they have time to work much mischief. Where the cultivation of Dahlias is more a matter of strengthening the supply of late summer and autumnal flowers for cutting rather than obtaining blooms of extra size and quality, it is advisable to plant the very free-flowering varieties in the Cactus, decorative, and pompon sections. All these are also fine subjects for large beds; a thin planting of Constance, for instance, filled in with Fire King makes a very effective bed, whilst in the pompons very effective combinations either in decided and well chosen contrasts, or in a mingling of the softer colours, as represented by such varieties as Countess von Sternberg, Dora, E. F. Junker, Fashion, Grace, Midget, and Pure Love, can be produced. E. BURRELL.

Claremont.

**Iris flavescens.**—This German Flag should be cultivated by all who admire this section of the Iris family. It is a very strong grower, the strongest of a collection of twelve varieties that were planted in clumps of six four years ago. *I. flavescens* has now developed into a mass 10 feet in circumference, which has this year thrown up thirty-five flower spikes of pale yellow flowers, which are more lasting than those of many of the other named varieties. The German Irises will grow in almost any situation, from a steep embankment to a moist bed, but it is necessary that they should be afforded opportunity of enjoying the sunlight. Good varieties are *Iris pallida*, *I. pallida dalmatica*, *I. flavescens*, *I. florentina*, *I. Madame Chereau*, *I. Prince of Orange*, *I. Princess of Wales* and *I. Queen of the May*, all of which are attractive forms. *Flavescens* is certainly the best doer of the foregoing, and if but one variety is grown this should be chosen, the best two for effective contrast being *flavescens* and *pallida*.—S. W. F.

**THE SWEET SULTAN.**  
(*CENTAUREA MOSCHATA*.)

This charming old annual is not often seen well grown in gardens, but it is a pretty flower for the garden or the house, and well worthy of the care needed to ensure its healthy growth.

Perhaps the most essential thing is that the soil contains lime, as if this is deficient the plants make a puny growth and flower prematurely or die altogether. Soils not naturally calcareous may be made suitable by the addition of lime rubbish. Another point is to sow the seeds where the plants are to grow, and as soon as they are large enough thin them out to about 9 inches or 1 foot apart. There are two distinct shades of colour, one pale purple and the other creamy white. The Sweet Sultan is much grown for the market. The flowers, with their long stems, are admirable for gathering, and their pleasant fragrance is not the least of their charms.

**ORCHIDS.**

**SCUTICARIAS.**

This is a small genus containing not more than three or four distinct species, but these are very remarkable Orchids in appearance and very

Sweet Sultan (*Centaurea moschata*).

singular in their manner of growth. Botanically they are closely related to *Maxillaria*, but the resemblance goes no farther than the flowers, the habit being entirely different. *Scuticarias* are all evergreen epiphytes with very short stems and long cylindrical leaves, found growing naturally on trees in equatorial America. The flowers occur on short stems; not usually more than three form one growth. These Orchids will grow in a *Cattleya* house temperature, but are far more satisfactory if treated to more heat, thriving well during the growing season with the deciduous section of *Dendrobiums*. A constantly moist atmosphere during this period is essential, and the plants must never be allowed to be dry at the roots, this latter being the most frequent stumbling-block to the successful culture of *Scuticarias*. The roots are fairly large and fleshy, and when covered with a little growing *Sphagnum*, no great amount of care will be needed, and this treatment will be found far preferable to bare blocks. They may be grown either in baskets or on blocks, but if the latter they must be of good size in comparison with the plants, as small blocks part with the moisture too readily, and do not give sufficient

root-hold. A good deal of sunlight is necessary for these Orchids, no flowers being produced if grown in a dense shade. They are not constant in their habit of growth or time of flowering, but if possible they should be fairly excited in spring so as to get the growths ripened as the sun is waning in autumn. The winter treatment of such plants consists in keeping them moist enough to prevent the leaves from shrivelling and dropping off, at the same time avoiding too much watering. Plants that grow away during the winter must be carefully treated, and a routine arranged as near as practicable to the conditions obtaining at their natural season, this being better than attempting to dry them when they seem inclined to grow, or to excite them when quiescent.

*S. HADWENI* is a somewhat rare and variable species, introduced in 1851 from Brazil. The leaves are usually pendent, occasionally erect, growing about 18 inches in length, pointed, and grooved on one side, deep green. The flowers are 4 inches across, the sepals and petals yellowish, blotched and barred with brown. The lip is broad, wavy on the margin and hairy; it is white, with rose markings. There are several varieties of this plant, differing chiefly in the disposition and tints of the spots. The best known kind in the genus is

*S. STEELI*, a most remarkable species, popularly designated the Whip Orchid. In this the leaves attain a length of 4 feet and upwards, not much thicker than a lead pencil in any part. The flowers occur in twos and threes, and are individually 4 inches across, pale yellow on the sepals, with chocolate markings, the lip creamy white, with bright purple radiating lines. This was introduced from British Guiana in 1834.

*S. KEYSERIANA* is closely allied to the latter species and is identical in habit, but bears larger and brighter coloured flowers. This was first exhibited by Messrs. Sander and Co. in 1888.

H. R.

**CYPRIPEDIUM CAUDATUM.**

This remarkable and beautiful Orchid is now flowering freely, and owing to the peculiar tail-like appendages from which the species takes its name it attracts a good deal of attention and admiration. It belongs to the *Selenipedium* section of the genus and produces from two to four flowers upon the scape. The culture of *C. caudatum* is not difficult, nor is the plant at all fastidious with regard to temperature, thriving well in the *Cattleya* house, but better in more heat or a full stove temperature. Here the plants positively enjoy life, producing stiff, leathery leaves of that beautiful deep green that all growers of *Cypripediums* like to see, the flower-scapes being also more vigorous and healthy. These green-leaved varieties do not seem so sensitive either to watering overhead; if not given too heavily or often, it is decidedly beneficial by clearing away accumulated dirt or insects. Soft, or rain water must, however, be used, as hard water leaves a white sediment behind on the leaves that is very disfiguring and difficult to remove. The compost for this Orchid must be very free and open, nothing in the least likely to become sour being retained. Fibrous loam and peat in equal proportions and with all sand and earthy parts sifted out, *Sphagnum* Moss and charcoal will be an ideal compost, and the drainage must have very careful attention. Water must be plentifully supplied at the roots at all seasons and the plants grown as strongly as possible, this being the true secret of success with this species. Small, puny growths have not the strength to flower well, if at all. As the plants get stronger and produce more vigorous growths, fine healthy flower-spikes will follow. The best time to repot is very early in spring, and although *Cypripediums* dislike being disturbed it is far better to repot biennially, or even annually if need be, than to allow the plants to sicken from the effects of a close, soddened compost. The typical *C. caudatum* is a native of Peru and bears yellowish

and brown flowers of varying tints, the colour usually brighter towards the tips of the petals. These latter have been known to grow to a length of upwards of 30 inches, the effect of a good plant in flower being very striking. The variety *C. c. Lindeni* is supposed to be a freak of nature or monstrosity. The lip of this form is said to be of the same character as the petals, instead of the usual pouch. This was found in 1848 growing at a great elevation on the Cordilleras in deep, shady woods. *C. c. roseum* is a very bright-coloured form, discovered by Warszewicz growing on the tops of trees in elevated positions in Chiriqui. *C. c. Wallisi* has shorter petals and is large and very distinctly coloured. The sepals are white, veined with green, and the lip is also white at the opening. R.

#### SEASONABLE NOTES ON ORCHIDS.

Up to the present season has been very favourable for the growth of Orchids, and the plants in the East-India house are looking especially well. *Dendrobium*s are growing very freely and can hardly be kept too moist at the roots, those that were reported having by now obtained a good hold on the compost. In order to give light and room for the new growths, we have cut away many of the old pseudo-bulbs both from the evergreen and deciduous kinds, as although these of the former may have given a chance spike or two, the advantages aforesaid are decidedly greater. *D. Cambridgeanum* has been making a pretty show and is getting past its best. The pseudo-bulbs are well finished and it will now be hung in a cooler, more airy structure, but still kept fairly moist at the root. After the leaves fall this species likes a short rest, and I have usually placed it in the open air for a time, returning it to the Cattleya house on the approach of cold nights, and when seen to be again starting placing in the warmest house. Plants of *D. chrysanthum* that are finishing their growths must not be dried, nor do they need the same amount of ripening as the deciduous species generally. The flowers are always finer and better in colour if the foliage is retained until they are nearly or quite open. *Cypripedium*s must be carefully shaded now, an hour's exposure to bright sunshine ruining the appearance of many of them, especially those with the darker, more tessellated foliage. These all require an abundance of water at the roots now, needing attention almost daily. What a gem is *C. Schlimi* where happily situated, the plants being nearly always in flower. The heat of the East India house is too much for this kind at this time of the year; but give it a position in a shady house that does not go much above 75 at any time, with a constant supply of moisture to the roots and it is indeed at home; here the spikes are finer and the foliage attains a much richer tint owing to the complete immunity from insect pests, impossible in a very warm house. In the Cattleya house *C. Mossia* is getting over, but *C. Warneri* and *C. Gaskelliana* are coming into flower. The old Brazilian *C. Forbesi* is apparently not much grown, nor can it compare with the *labiata* section for size or brilliance of colouring. It is a slender growing species, somewhat resembling *C. intermedia*, but the flowers are yellowish with purple markings on the lip. The latest plants of *Miltonia vexillaria* are now showing the buds, the earliest being over. This species does not rest very long as a rule, the growths appearing at the base of the flowering pseudo-bulbs soon after their beauty is past. There need be no hurry in repotting the plants, a suitable time being late in August or September, when the growths are well on the move. Cleanliness is, however, necessary at all times, and frequently, owing to the dry atmosphere of the flowering house, thrips make a little headway at this season. If this is seen to be the case, no time should be lost in effecting a riddance of them before they attack the young shoots, for if they are allowed to do this, no after treatment will be really effectual. *Anguloa Clowesi* is now flowering in the cool house, the peculiarly constructed lip being very attractive; on account of its rocking motion it has

gained for these the name of Cradle Orchids. These like a substantial compost and should be seen to immediately the flowers fade. Rough fibrous peat and loam with chopped Sphagnum and potsherds will grow them well, and as they require abundance of water, the drainage must have special attention. *Odontoglossum citrosimum* is growing freely, and as the cool house is so heavily shaded, we grow this in the cool end of the Cattleya house, the additional sunlight and heat causing a more solid and therefore floriferous habit of growth. The *crispum* section, and also *triumphans*, *luteo-purpureum*, and others of this class cannot now be kept too cool, a free growth of the Sphagnum about the bases of the pseudo-bulbs being also of great advantage.

Fire-heat has now been dispensed with in all departments, the warm house not falling below 60, though a little air has been left on the lower ventilator. This induces a fresh, cool night temperature such as all Orchids delight in, the moisture collecting on the plants in the form of dew keeping them cool till well on in the day. The Cattleya house is kept as near 55° as possible, though a few degrees less does no harm, and the cool house is left wide open at night top and bottom, nearly closing it during the day and shading heavily. H. R.

**Epidendrum Wallisi.**—This very interesting species grows from 4 feet to 6 feet in height, and it is seldom so fine a specimen has been seen in bloom as that in the collection of Mr. G. Fowler, of Glebelands, Woodford. This specimen has eight fine well-developed spikes of flowers, which are exceedingly showy and effective. The blooms each measure about 2 inches across; the sepals and petals clear bright yellow, spotted sparingly with deep brown; the lip large and spreading, white, streaked and spotted with purple, with three prominent raised lines of yellow at the base. The stems are erect and slender, and spotted with a purplish colour between the nodes. This desirable plant is a native of New Grenada, where it grows upon the Western Cordillera at some 5000 feet or 6000 feet elevation. It is one of the finest kinds in this large genus, and will continue producing flowers for several months in succession. —W. H. G.

**Maxillaria tenuifolia**—This quaint little Orchid is now in flower, and fills the house with its peculiar perfume. This is different to that of any other kind that I know of, and has been likened to salt butter. The pseudo-bulbs of this species are produced one above the other on the erect rhizomes, and unless given new compost about every third year they soon get weak. The foliage is long and narrow; hence the specific name. It flowers freely, and the flowers are about a couple of inches in width, bright yellow, spotted all over with crimson. Being small and not particularly showy it is not much grown, but one occasionally comes across a good specimen, and when covered with the bright little flowers they are by no means unattractive. It is very easily grown, thriving in the coolest part of the Cattleya house in pots with a mixture of peat and Sphagnum. Plenty of water is needed while growing, and even during winter they must never be dried. *M. tenuifolia* is a native of Mexico, having first flowered in England at Chiswick in 1839. —R.

**Odontoglossum Alexandræ** was one of the principal features at the Temple show last month, when several novel and rare forms were shown. Independent of the finely spotted varieties there were some pure white kinds of exceptional merit, and which would make admirable companions to *O. crispum virgale* mentioned in THE GARDEN of May 18 last. The best was perhaps that shown by Messrs. Sander and Co., of St. Albans, and which was named *O. crispum Duchess of York*, the raceme carrying a fine spike of bloom. The individual flowers, although somewhat small, were of the purest white, excepting a golden yellow disc on the lip. Another variety shown by Baron H. Schneider named *O. crispum xanthotes* was also remarkable for its chaste and pure white

flowers, which, although of larger size and better substance than the above, were not pure white, having in addition to the yellow crest a few very pale yellow spots on the sepals and petals; this, however, marks it at once as one of the most distinct. This may not be a complete list of the pure white varieties, but they do not appear to be at all numerous; the majority, although having pure white sepals and petals, are more or less spotted with reddish brown on the lip, or have the segments flushed with a mauve tint. These white and tinted varieties are mostly found in localities lying from about twenty to thirty miles south of Pacho.—W. H. G.

**Lælia grandis tenebrosa.**—This splendid variety of *L. grandis* is apparently far from constant in its time or manner of flowering. I have known it to flower at once on the newly formed pseudo-bulbs after the manner of *Cattleya labiata*, but more often it rests through the winter, carrying the sheath and produces its flowers late in spring or early summer, like *C. Mossia*. But whenever the flowers come they are invariably welcome, the rich tints of purple and rose being very distinct and of an unusual character in the genus. The plant is of a strong, erect habit of growth, the pseudo-bulbs varying a little in form, and each bearing a fine large leaf. No difficulty will be found in its cultivation in a house where the usual run of *Cattleyas* and *Lælias* are satisfactory, but for preference a large, roomy structure should be chosen. Rather large pots should be used, as the roots are exceptionally vigorous and of a rambling tendency, and the compost must be well aerated and used in a rough condition. Though liking a good clear light, it must not be placed too near the roof glass, being more satisfactory at least a yard away. The flowers are large and showy, each measuring 7 inches across. The sepals and petals are spreading, brownish purple, and the lip is broad, slightly frilled at the margin, deep purple. There is, however, a good deal of variation in the flowers, but all are strikingly beautiful.—H.

#### CYCNOCHES CHLOROCYLON.

The Swan Orchids, as they are popularly known, are not remarkable for either showiness or bright-colouring, but several of the species are very interesting and possess considerable beauty. The species under notice is perhaps as much grown as any, and will compare favourably with the others as a garden plant. It has stout, fleshy green pseudo-bulbs, which on strong plants attain a height of about 15 inches, and these bear several broad leaves upwards of 1 foot in length. The flowers are produced in curving racemes, each carrying from four to ten, individually about 5 inches across. The sepals and petals are yellowish white, the lip pure white, with a yellow or green blotch in the centre. The column is slender, elongated and curved, the end containing the pollen, swollen into an irregularly oblong knob. The plants usually grow well the first few seasons after being imported, but frequently show a disposition to go back afterwards. This is not always the case, as I know of plants that have been under cultivation for at least a dozen years, and these are really better now than they were five years ago when I first saw them. The chief points in their culture are good drainage and a very distinct resting and growing season. They are best grown in pots in a compost consisting of good loam fibre, chopped Sphagnum and peat in about equal proportions, with a few small pieces of potsherd or charcoal to ensure a sound and well aerated medium. They like a light position and plenty of heat and atmospheric moisture while growing, being well suited if given a place alongside the deciduous *Dendrobium*s, care being taken that the foliage does not suffer from too bright sunshine. This will not occur if the atmosphere is properly moistened at closing time, as a film is thereby caused to collect over the glass sufficient to keep them safe. From the time growth is well on the move until the pseudo-bulbs are complete they cannot well be over-watered if

the drainage is good, but avoid wetting the leaves with the syringe, as the water is very apt to collect in the young growth, causing this to decay. As soon as the leaves begin to turn colour in autumn the water supply must be diminished and almost wholly withheld during winter. At this season the plants are best in a light, airy house that never falls below about 52°, as if kept too cool there is a danger of a black spot attacking the pseudo-bulbs, which is very difficult to arrest if once it obtains a hold on the plants. Early in the new year the new growths will be seen to be starting and the compost should then be put in order if this is necessary. A thin surfacing of Sphagnum Moss is beneficial, as it keeps the roots moist without continual waterings, and the plants must be at once placed again in the warm house, when they will flower about the present time. *C. chlorochilon* is a native of Demerara, whence it was introduced in 1838. H. R.

## KITCHEN GARDEN.

### VALUE OF DEEP CULTIVATION.

THE present season undoubtedly shows the advantage of deep digging, for in districts where but little rain has fallen the crops on ground that was not well tilled are in anything but a satisfactory condition. In this neighbourhood we have only had just over a quarter of an inch of rainfall since April, and the soil has got so dry in places that the Grass presents a burnt-up appearance. In gardens also where the ground was not deeply dug the crops are suffering seriously from the effects of the dry weather. Early Peas that should be at least 4 feet high have not exceeded 18 inches, and many others in like manner show the want of nourishment in the soil. Where ground was deeply dug and well worked, the roots have been able to penetrate in search of moisture, and on such vegetables in general are looking well. Potatoes with us have never been more promising, as we had no late spring frosts this season to injure them. Peas, though a little late, are doing well, and except for the slugs, which were so troublesome in April, would never have been better. Gradus that was sown in pots and planted out in March is now giving us a good supply; the same may be said of the Duke of York. These Peas were said to be of medium height, but with me they are quite 5 feet even in this dry season. They do not grow the same in all gardens, however, for in some in this district the haulm is not more than 18 inches, but the ground had not been either deeply dug or well tilled; hence the dry weather has taken hold of them. Cauliflower in some places is almost a failure, but where the ground was in good heart and deeply dug they look well; the same may be said of Cabbage and others of like nature. There is a vast difference in the crops on poor, shallow ground, for many of them look very sickly, even where water has been afforded them, to say nothing of the extra labour entailed in such work. Where the soil in kitchen gardens is shallow, every means should be taken to increase its depth, and though this cannot always be done in a season or two, still with perseverance in due time it may be rendered fertile to a depth of 2 feet or even more. I would not, however, recommend trenching, so that the poor barren subsoil is brought to the surface, but by adding manure and loosening up the ground an inch or two more each season, there will soon be sufficient depth for the roots of most crops. Digging is usually done at a time of year when work is not so pressing; therefore there is no reason why pains should not be taken to do the work well. Most old gardens were well made in the first instance, for where the soil was shallow more was added till a sufficient depth was found for all crops, and this to some extent accounts for the excellent vegetables produced in them. There are, however, favoured places where the soil is naturally fertile for some depth if it were only handled in the right manner. I have long advo-

ated deep cultivation for all vegetables, and though some are only shallow rooting, they may be succeeded by others that require a considerable depth of earth to grow them well. If ground is properly dug in wet seasons this will act as drainage by allowing the superfluous moisture to pass through, while in dry seasons the roots are able to penetrate to such a depth that the weather has but little effect on the plants. H. C. P.

**Preparing for winter Onions.**—This note may seem uncalled for at present, but from the fact that the firmer the ground is at sowing time the better chance the crop has, timely preparation is certainly advisable. It is a good plan to utilise the plot from which early hand-light or the first transplanted Cauliflowers have been cleared, and as this has been subjected to a continuous traffic since last autumn in order to attend to the wants of the plants, air has to a great extent been excluded from that portion between the rows. This plot, therefore, needs turning up and exposure before another one is sown or planted on it, and winter Onions will be the best to follow the Cauliflower. Sometimes Cauliflower roots are much infested with grubs, and a percentage of these pests are, of course, left in the ground when the old stumps are pulled up. These need eradicating, and in the necessary preparation for the Onions this is effectually done. In the first place wheel on to the plot an abundant supply of good manure, a fair amount of soot, a little gas-lime, and if at hand some burnt refuse or wood ashes. Then take out a good wide trench at one end some 15 inches in depth, and after spreading and mixing all the ingredients on the surface proceed to throw forward the soil into the trench, thoroughly incorporating the manure, soot, and lime as the work proceeds. Thus the young seedlings will have a rich larder from the start instead of having, as in the case of ordinary trenching, to wait until three parts grown before the roots reach the manure. Trenching completed, give a good treading, repeating it in a month's time and again at sowing time.—C. N.

**Good dry weather Potatoes.**—Various Potatoes, like some sorts of Peas, stand a dry season far better than others, growing better and not giving way so soon. As belonging to this section may be mentioned Early Puritan and Snowdrop. These two varieties are doing well with me on a light soil and with an almost total absence of rain for many weeks. Both Snowdrop and Puritan have now (the second week in June) good tubers fit for lifting, the sets having been planted in the third week in March, and growth, of course, protected. Snowdrop ought to be more largely grown, it being a good cropper, handsome, and of unsurpassed flavour, and keeping well until Potatoes are ready again in spite of its being a second early sort. Mr. Tallack, of Livermore Park, last year wrote in praise of Snowdrop, it being, if I remember right, his favourite Potato.—J. CRAWFORD.

**Chilies and Capsicums.**—These are much valued in many gardens, especially where sauces and pickles are a speciality in the dining-room. The plants will now be in free growth, and will need shifting on into pots a size larger before they become in the least pot-bound. A moist growing atmosphere is essential for their well-being, means being taken for preserving the foliage free from insects. Both spider and green-fly are great enemies of the Capsicum, thus necessitating the free use of the syringe twice daily. Sometimes the fruits set too freely, and if all are allowed to remain till matured, the plant makes poor growth, and the weight of fruit in the aggregate is smaller than when judicious thinning is practised. The yellow varieties grown by some for ornament are most attractive in autumn and well repay good culture. Good loam and a free admixture of rotten manure suit them best, feeding with farm-yard manure water tending to increase their vigour when once the pots are becoming filled with roots. Do not expose the plants to the full blaze of the sun, or the foliage will lose its deep green

colour and be liable to sear should it be caught in a wet condition. Towards autumn as soon as the fruits are three parts coloured removal to a cooler and more airy house is advisable.—C. N.

**Grubs in Cauliflowers.**—How often these are affected by a small white coloured maggot which clusters in colonies around the lower part of the stem and roots. This pest is often the cause of failure in batches of Cauliflower, which until three parts grown and about to heart in look splendid. I have often thought that, in addition to dressing land addicted to this enemy with gas-lime, burnt refuse and soot at digging time, it would be well when planting to mix a percentage of these ingredients with the soil round the roots, as all grubs and similar pests are certainly opposed to such a mixture. It is not a good plan to replant a plot directly Cauliflowers which have been affected with this maggot are cleared off. The better plan is to well dress it and allow it to remain uncropped six weeks, although of course when ground is scarce this cannot always be done.—J. C.

**Carrots.**—Where wireworm and grubs have made gaps in the main sowings of Carrots, it is not too late for sowing again, providing proper sorts are sown. Scarlet Model, Nantes Horn and Market Favourite will do well, being quick growers. Prepare the ground thoroughly by incorporating plenty of soot, wood ashes and burnt garden refuse, this being obnoxious to all insect pests and promoting a vigorous growth. It is also a good plan to sow small batches of some quick-maturing Carrot several times during the summer, these being most useful for drawing in quite a young state. Odd corners or nooks not large enough for any other crop may be used for them, as it is not large quantities that are needed, but a succession of young sweet roots.—J. C.

### THE ASPARAGUS KNIFE.

MR. KEMP shows on p. 362—and many of us have proved by thousands of examples in practice—that the knife is wholly unnecessary. True, a little tact and knowledge of the roots and shoots of Asparagus are needful to deftly twist them off at the right point without breaking the crisp shoot through at the wrong place; but this art is soon acquired, and we get a maximum of edible grass with a minimum of injury to the growing roots and succession shoots. The blind, blundering knife, even in skilful hands, can hardly escape serious injury to both, whilst the knife in ignorant hands has maimed and ruined tens of thousands of promising Asparagus beds.

No sort of knife is needed for gathering Asparagus shoots on or near the level; hence the abolition of the knife in Asparagus grounds will also deliver the plants from that living death and semi-burial to which so many of them are subjected. The depth of this crown burial varies from 6 inches to 2 feet. Last autumn afforded special facilities for observing on a large scale the autumnal or winter dressing of commercial Asparagus well known in our London markets. That dressing consisted of a soil covering over a foot deep to a mat of weeds that covered the surface. The beds were 3 feet wide, with alleys between, and there were two or three rows of plants on each bed. The soil was dug out of the alleys and heaped over the weeds, leaving thousands of roots wounded and bleeding in the process. And yet it was said on the spot that this dressing was the only manure these Asparagus beds had had for twenty years. If so, the vigour of the plants furnished marvellous proofs of their powers of endurance. Many of the crowns must have been 18 inches or more from the surface. This system of heavy soil dressings in the autumn and winter to be raked partly down in the early spring also largely prevails in other parts. Without further discussion as to its benefits or otherwise, I only remark here and now that it renders the abolition of the Asparagus knife almost impossible. For Asparagus differs from most other plants in this. Blanch most of these, the more crisp, sweet, and

tender they grow. Blanch or bury Asparagus, and it is tough, tasteless, and useless, unless as a handle to the depths blanched. This woody consistency of blanched shoots, as well as the obstruction of the over-happy soil, would render impossible Mr. Kemp's quick and easy method of gathering Asparagus on the flat. No doubt his recommendation, which I heartily endorse, will be gladly adopted by many, to the great improvement of their Asparagus through its dual deliverance from burial alive and the knife.

D. T. F.

**Autocrat Pea.**—This comparatively new Pea is, I think, destined to become a general favourite. One good point in its favour is the free, stout growth it makes on light warm soils. Many of the strong growers, while doing well enough on ground which contains plenty of moisture, soon give way at the bottom of the haulm on shallow soils during dry weather. I have sown Autocrat on an open border at the same time as the early varieties, and it grows well thus early, and following these closely, comes in most useful, being a fine Pea of delicious flavour and a profitable cropper. I have also sown it at the end of February or beginning of March with such well-known sorts as Stratagem, Stourbridge Marrow, Exhibition Marrowfat and others, and it can hold its own with them all. The produce from this sowing has enabled me to prove its great resisting powers. It is also useful for sowing in June along with No Plus Ultra for late use.—J. C.

**Veitch's Extra Early Foreign Cauliflower.**—On January 28 I sowed with other seeds a pinch of the above, and as soon as the plants had made their rough leaves, they were pricked into boxes and ultimately planted out on a south border without the slightest protection, with the exception of what the wall afforded. By June I could have cut nice little heads of snowy whiteness, but my supply of Late Queen Broccoli was not exhausted; therefore I was not anxious to begin cutting for a few days. In our case this year this Cauliflower will over-lap Late Queen Broccoli a fortnight. I have grown several varieties of early Cauliflowers, but none have proved so early and reliable as this. Veitch's Pearl sowed the same time is now very robust-looking, and will, I have no doubt, follow close after the above. I consider these the two best and most reliable early Cauliflowers grown, and with me they do away with the necessity of autumn sowing.—J. EASTER, *Nostall Priory Gardens.*

## BOOKS.

### A DICTIONARY OF HORTICULTURE.

HAVING but a few days ago had the opportunity of reading the *critique* by "W. M." in THE GARDEN on M. A. M. C. Jongkindt Coninek's work, "A Dictionary of the Principal Terms used in Botany and Horticulture," may I ask you to give me space to say a few words in reply?

As an old pupil of M. Coninek's, and one who has given him some little assistance with the "Dictionary" by revising the English part of it, it is natural that I should take some interest in endeavouring to bring out its merits before those who, like "W. M.," are unable to see the useful side, or the *raison d'être* of such a work. Doubtless, as "W. M." points out, it would be extremely useful to possess a polyglot dictionary of common gardening terms, such as "bell-glass," "layering," "mulching," &c., and I for one should hail such a work with satisfaction. But in compiling his dictionary M. Coninek has entertained an entirely different notion of the needs of the present-day horticultural world. He has perceived that a correct knowledge of the names of plants, together with the terms used in describing them and their immediate equivalents in the various languages, is of far more importance to the rising generation of plant growers than a compilation, however well planned, of such common

horticultural terms as "W. M." has named. Technical education of this kind will be proved in the long-run to be a *sine qua non* as well to the nurseryman as to the agriculturist, and by the publication of his dictionary M. Coninek is undoubtedly helping to spread broadcast this necessary element.

A dictionary of this kind, and not one such as "W. M." has proposed, well and proper as the latter would be in its place, supplies such information as will enable plant growers to correctly name their plants, to understand these names, and to give, when occasion requires, a true and definite description of the plants in the different languages.

In contemplating the evident practical usefulness of such knowledge, it seems to me high time that nurserymen and gardeners began to take a more intelligent interest in the individual characters and needs of the plants they cultivate, and these characters and needs are often revealed in the generic or the specific name of the plant.

As M. Crépin justly remarks in the preface to this little book, its value largely lies in the fact that it will save the continual fumbling through voluminous dictionaries. Moreover, contrary to what "W. M." has asserted, the equivalent English, French, German or Dutch translations of very many of the words, as I myself have often found by experience, are not to be discovered in ordinary Latin dictionaries, of however high a standard they may be, and it was usually only after searching through scattered botanical works that the proper terms were obtained.

M. Coninek's work is not a "Dictionary of Horticultural Terms," but a "Dictionary of the Principal Terms used in Botany and Horticulture," and its arrangement is such as to render easy an acquaintance with these terms in the various languages.

But I am not alone in my conception of the value of this work. Is the consensus of opinion of twenty-three of the leading horticultural papers in Europe to count for nothing? And how is it that the adverse criticism of "W. M." is the only one which has been forthcoming?

I am confident that it is the technical botanical knowledge which in the future will produce capable cultivators, and will tend to effect the interchange of sound and scientific ideas between the various nations of the horticultural world.

The *raison d'être*, then, of this work is sufficiently evident, and at some future time we will hope to see it revised and amplified, some of those terms which are less directly useful being omitted and others included in its pages.—W. C. W.

—In the latter half of his communication "W. C. W." fully admits all that I have advanced. Only a dozen or so of horticultural terms are given. Anyone who cares to trouble himself about the matter should get a copy of M. Coninek's dictionary and look through it, and then read what I said about it in THE GARDEN. I am quite content to abide by the judgment of any sensible man as to the justice of my remarks when he has done this.—W. M.

**The Horticulturist's Rule-Book.\***—A book that deals with the best methods of waging warfare against the many fungoid and insect pests that are ever present and ready to discount our best endeavours is bound to be of service. A vast amount of useful information as to pests and remedies lies scattered that it is most desirable to have collected in a handy form available for ready reference, and we have it in this manual which, originally compiled in 1889, has now reached its third edition, which is revised and up to date. The author remarks "that the contents have been gleaned from many sources," and such a mass of useful information is the result, that the book should become a standard work of reference essential alike to all who have to deal with plant life, whether for pleasure or profit. The first chapter deals with insecticides, and others follow on injurious insects, with remedies and preventives,

\* "The Horticulturist's Rule-Book." By L. H. Bailey. Macmillan and Co., London and New York.

plant diseases and remedies, injuries from rodents, lawns, weeds and moss, waxes for grafting, cements, mortars, paints and glues; with many more chapters containing seed planting and computation tables, rules and useful items of information, all tabulated alphabetically and indexed for ready reference. The price of the book, which is only 75 cents, happily places it within the means of all who may happen to need it.

## GARDEN FLORA.

### PLATE 1019.

#### THE GLADIOLUS-FLOWERED CANNAS.

(WITH A COLOURED PLATE.\*)

No class of plants grown for the sake of their flowers has come more prominently to the front than have these beautiful forms of the Indian Shot during the past two or three years. This dwarf race of Cannas with large trusses and proportionately large flowers originated in France, M. Crozy, of Lyons, being the introducer of these fine decorative flowering plants. One of the first varieties to be certificated in this country was Mme. Crozy, which received that award in 1890 when shown by Messrs. Paul and Son. The same firm during the following four years received for other varieties no less than nineteen additional certificates. This fact alone is sufficient to indicate the progress that has been made in this race, variation in colour both in selfs, margined and spotted kinds being particularly noteworthy. In its way, however, Mme. Crozy still holds its own; its bright crimson flowers edged with gold make it conspicuous, the petals being individually large and the habit dwarf and compact. Another and more recently introduced variety is Konigin Charlotte (W. Pfitzer), which must be deemed one of the very finest yet raised, having all the good qualities of the preceding with larger trusses and in greater profusion. It is of vigorous, yet very dwarf growth, the massive foliage adding to its beauty; its spikes are borne well above the leaves, the individual flowers being large, bright red in colour, with a broad golden or canary-yellow margin. This variety recently at the Temple show was shown in the finest condition by Messrs. H. Cannell and Sons, Messrs. H. Low and Co., and Messrs. Paul and Son. It may be so grown as to flower at almost any season of the year, but this is scarcely desirable. Another notable variety is Cheshunt Yellow, which was the first English raised Canna to receive a certificate of merit. It is a great advance in the pure yellows with compact spikes of bright clear yellow flowers, and, like the preceding, is also well suited to either pot culture or for bedding out. As an example of the spotted forms, Amiral Avellan should be noted; it has large clear yellow flowers, spotted profusely with red. Another beautiful spotted kind is found in Antoine Barton, in which the ground colour is also yellow, but with carmine spots. Of the self-coloured varieties note should be made of Alphonse Bouvier, deep crimson, very dwarf; Sophie Buchner, bright vermilion, a very fine variety, with handsome foliage as well; Primrose, clear lemon-yellow, very distinct and free; Baron M. de Hirsch, crimson-scarlet, with yellow border; Paul Bruant, rich violet-crimson; Emperor William 2nd, bright scarlet, an extra fine variety; and Tom Thumb, which bids fair to be the forerunner of an even dwarf

\* Drawn for THE GARDEN in Messrs. Cannell's nursery at Swanley by Agnes Cook. Lithographed and printed by Guillaume Severeys.

*Asplenium platyneuron* L.  
1. Spore. 2. Prothallium. 3. Young plant.

race, flowering freely when not more than 1 foot in height. The foregoing are a selection of one dozen of the best kinds typical of this new race; others could be added, for already, as in other instances, the new varieties are becoming very numerous, too much so in some respects when the variation is but slight. As regards

CULTURE,

we cannot do better than quote the advice given by Mr. George Paul in a paper read before the Horticultural Club in November, 1893, wherein he states:—

The outdoor culture of the Gladiolus-flowered Cannas is simple. Prepare the ground as for Dahlias, choose young growing plants, and plant, if on a lawn, in large beds about 3 feet apart, in rich soil; and, beyond some watering to establish the plants and a possible mulching if the weather be dry, nothing more is needed. The earlier they are planted out the better, as long as it is past the time of May frosts. They soon flower and keep on until they are either cut down like the Dahlia, when they may be either lifted and stored in a similar manner, or, better still, they can be utilised for winter flowering. . . . I think the secret of pot culture is alternating the periods of growth and rest. The constant potting of the plants into larger pots, say three times a year, is to be deprecated, as they become specimens too clumsy to handle; but if kept in the same pots they should be heavily and highly mulched. Soil: Sandy loam and rotted manure. They take much water, like most large-leaved plants, but need good drainage.

To these remarks it should be added that increase is readily effected by division of the rhizomes, each leader of which will make a plant. Seedlings also are easily raised, this process giving prospect of variety. To flower these Cannas early in the season, i.e., from March onwards to May, a gentle heat is necessary, with a fair amount of atmospheric moisture; light also is essential to preserve a dwarf growth. If it is deemed desirable to cut the spikes, it is well to state, for the benefit of those who have not noted it, that in so doing the secondary spike which emanates from the base of the first may thus be cut away, the plant being thus shorn of a part of its beauty.

H. G.

ORCHARD AND FRUIT GARDEN.

APPLE JUNEATING.

This early Apple is sometimes known by the names of Margaret and Early Red Margaret, and wherever grown it is greatly appreciated for its earliness, pretty colour and pleasant flavour for dessert. Old people whose teeth are not very good are especially fond of Juneating, as the flesh is soft, very juicy and just the sort of Apple they like. Soil and situation affect the shape of the fruit to some extent, as in some counties the fruit is very round (as in the illustration), while in some other parts it comes slightly angular. In two orchards here we have the fruit different in shape, though exactly similar in colour and taste, which proves that the soil does influence the form of the fruit. A landowner who desires to plant an orchard of Apple trees for his home supply should include Juneating in the selection of varieties, as it is one of the best and earliest dessert sorts that could be planted. Seasons naturally hasten or retard the ripening period. Twice within the past ten years I have gathered this variety at the end of the second week in July, and in cold, wet years the fruit has not been ready until a month later; but

even if the Apples are not ripe before the second week in August, there are so very few really good dessert Apples ready then that Juneating is valuable, affording a welcome change on the dessert table. Another excellent recommendation is the fertility of the trees, particularly those in standard form. This arises from several causes, the greatest being the early maturing of the fruit. Any kind of fruit tree that ripens its crop very early is relieved of its load some months before the fall of the leaf, which enables it to recover in a great measure from any exhaustion experienced in perfecting its fruit. I could mention several well-known kinds of fruit that are universally known for their heavy and continuous crops, all and each of which ripen their fruit early like the Juneating Apple. Again, the early removal of the crop throws the full energy of the tree into bud-formation, and unless climatic conditions are very bad indeed the fruit buds are so strong and well formed, that a good set is practically assured. Trees of Juneating are moderately strong growers, and standards will not become too crowded at 25 feet apart each way, as the soil must be of the most fertile character to promote a growth that would cause the trees to touch each other at such a distance. Another reason for their moderate growth is, as already stated, the prolific habit

Apple Juneating. From a photograph sent by Mr. J. Norman Blake, Bedford.

of the trees. I have only had experience with half-a-dozen bush trees of Juneating, but they have been equally as satisfactory in every respect as standards, while some cordons have not answered, the growth, foliage and fruit being decidedly poor in spite of extra care and attention to the roots. Possibly the latter trees have failed through being worked upon the French Paradise stock. W. G. C.

**Watering wall trees.**—Owing to the long drought, which has every appearance of continuing at present (June 11), wall trees are exhibiting signals of distress even where mulched. Not only does the foliage begin to look pale in colour, but the fruit is also assuming an unhealthy tint. In this part (Herefordshire) our rainfall is over 3 inches below the average for the year, or in other words, over 300 tons per acre short. In the open ground this is a serious deficit, but against walls it is more so. Not only do wall trees get generally less water when it rains, as the wall itself prevents it when the wind is in certain quarters, but the evaporation is greater than in the open ground, consequently they suffer more or less during a period of drought. If water is plentiful and labour can be spared to apply it, a thorough soaking to the roots will prove of intrinsic value to the trees, conferring a present and future benefit on them. Trees that lack moisture at the root can neither develop their fruit nor form good fruit-buds for another season, and the foliage is certain to be

attacked by insect foes. Already aphid in different forms is infesting Plum and Cherry trees. Red spider is becoming much in evidence on almost all wall trees that have suffered through lack of moisture—in fact, when once a tree gets into a weak state through any cause, insect enemies are sure to be particularly severe upon it.—W. G. C.

**Gooseberry Keepsake.**—The Gooseberry crop is not a very heavy one this year, but they are unusually large with us, even the smallest-berried varieties being larger now than is the case most years when ripe. The first to pick this season was Keepsake, which was a week earlier than its rival, Whinham's Industry. As I stated in THE GARDEN a year or so ago, Keepsake was and is probably now very extensively grown at Toddington, on Lord Sudeley's fruit farm, Mr. Wise, who so ably manages the estate, informing me that it was the best Gooseberry they grew. After some nine years' experience of it and other sorts, I must endorse the opinion of Mr. Wise, as the Keepsake, in addition to the good qualities already named, rapidly forms a large bush if planted on good soil and well treated afterwards. Again, most gardeners will have observed how some varieties of Gooseberries are always the first to be attacked by the caterpillar and red spider, which quickly spreads to other trees unless checked. Whenever these pests appear I have observed that Early Sulphur is the first to be infested, and Keepsake the last, an item of some importance with a Gooseberry that is marketed while green. Not only is the variety of value to the grower for sale, but equally so to the gardener who has to maintain a continuous supply of fruit for his employer's table. Most of us know how frequent the inquiries are, "When will the Gooseberries be ready?" some cooks putting this query almost as soon as the embryo berries are formed, thus proving how acceptable early fruit will be. As a change from Rhubarb or late Apples, Keepsake is an acquisition to the gardener in a private establishment, enabling him to pick berries early, or, what is sometimes of vital importance to him, as soon as they can be got anywhere.—W. G. C.

YOUNG STRAWBERRY PLANTS FOR EARLY FRUITING.

Those who require early Strawberries in the open would do well to plant young plants yearly for the purpose. So far I have found Noble by far the best, the fruits being very fine and quite ten days earlier than those from older plants. Noble planted on a warm border specially for the purpose will give a splendid return when Strawberries are none too plentiful during the first or second week in June. The land should be well cultivated by deep digging, with abundant manure, but even then these results must not be expected from weak, puny plants. I have for a few seasons adopted an easy plan to get strong young plants for the first crop in the open. I obtain my forcing runners from plants specially grown to produce them, and, wanting large numbers, have to purchase a few hundreds for planting in the open. As it is out of the question getting them strong or early enough to plant out then, the plants are potted when they arrive, placed under a north wall, and kept for early spring planting in March. Such plants are a little longer about, but it is a great gain to have strong plants with a mass of roots instead of weakly runners deficient of roots, a portion being lost in severe weather, and those left weak and not in condition to fruit the first season. Those who do not wish to pot up may plant them close together in rows and lift in the spring with a ball, but I favour pots, as then there is no cheek, and if carefully planted growth is rapid, and the plants by the following spring will be equal in size to three-year-old plants, but with more vigour, giving very fine fruits. If strong runners can be obtained in June or early in July, then fine fruits may be had in less than twelve months from time of planting. This is the best method, and in garlens where

the runners can be obtained very good results will follow. Though the crop will not be so large as from plants given a few more months, if the time the ground is occupied be taken into account, I would strongly advise this mode of culture. My reason for adopting the first named plan is potting up runners in August, or even September is more convenient, and runners when received from the trade grower have never many roots; a few hundred plants are soon potted up, and make fine material for spring planting. The plants are plunged in the soil over the rims of the pots in early winter, the flower-trusses removed when they show in the spring after planting out, and they are given ample space in the rows when planted. Noble is the very best Strawberry I have tried for the purpose named, as it is vigorous and free bearing, and though the quality may not be first-rate, I have never had any objection on that score, as early fruits are not expected to be equal to those ten days or a fortnight later. To get Strawberries early there must be vigour, only one fruiting season must be allowed, with the ground specially prepared. If time or circumstances do not permit of growing in the shorter period, the system advised is well worth a trial. In all cases the value of young plants is well known, much better results being secured, such plants often succeeding where older plants fail.

G. WYTHES.

**Pruning dwarf Apple trees.**—There are three ways of pruning dwarf Apple trees in vogue, and no doubt all have very good results generally, though none seem to show better average crops than do the dwarf trees at Chiswick, where the method of pruning does not consist of shortening the shoots or branches, but in keeping them well thinned out, so that the trees have a loose and, in some cases, almost drooping growth. It is rare that these trees do not carry a good crop. In some gardens dwarf trees have their branches thin, but hard-spurred, treated really as if cordons; in others the trees are repressed, by having the branches as well as the shoots shortened, so that in time they become stiff stocky bushes. It would be very interesting, had we gardens at our disposal, to test the relative values of all three systems on the same sorts of Apples side by side.—A. D.

**Cardinal, Early Rivers and Lord Napier Nectarines.**—Whilst most ready to admit that Early Rivers is a splendid early Nectarine, I confess not liking to see it exalted at the expense of Lord Napier, quite one of the best in cultivation. At the Temple show, apart from the fine collection of pot trees of Cardinal and Early Rivers shown by Mr. Rivers, and in another tent, was a small pot tree of Lord Napier having a few half-grown green fruits on it. By its side were dishes of the new Cardinal, and beside also a card, stating that this tree of Lord Napier had been subjected to just the same treatment as the trees which bore the ripe Cardinal fruits. The natural inference was that Cardinal identically treated was fully four weeks earlier than Lord Napier. Then it was not evident that Cardinal in the group was any earlier than Early Rivers—indeed, I do not learn that it is held to be earlier. Somewhat sceptical as to this immense difference between these two sorts and Lord Napier, and seeing close by some fine fruits of the Early Rivers and Lord Napier from that first-class fruit grower, Mr. McIndoe; thinking, too, it was very likely that these came from the same house, I ventured to write to him and ask the conditions under which these fruits were grown. I have from him a most courteous reply, in which he states that the two varieties were gathered from trees grown in a 70-foot lean-to house at Hutton Hall, side by side in the middle, and, of course, getting exactly the same heat. The house was started December 1; the first fruit of Early Rivers was gathered on May 11 and the first from Lord Napier on May 16, or only a difference of five days. This period corresponded exactly with what was found in ripening last year. It is but right, in the face of what was shown at the Temple, this impartial testimony as to the

relative earliness of these two fine Nectarines and the new Cardinal should be made known, as also Mr. McIndoe's testimony that there can be no doubt about Early Rivers being a splendid addition to the many fine varieties raised at Sawbridge-worth. The moral of this information is that with Early Rivers first, Lord Napier directly follows in succession.—A. D.

**Spraying trees, &c.**—One of the things we are continually preaching is the importance of checking the depredations of insects and fungi by the aid of antidotes sprayed over trees and crops. The preaching is tacitly admitted to be the thing, but is rarely acted upon. If we are to credit all we hear from the American orchards, it would seem as if the special function of the fruit grower across the Atlantic was one long contest, through the aid of spraying, with insect life. Here there is often ample need for the warfare, and yet it is little waged. Already do we hear in various directions complaints of the prevalence of caterpillars on Apple trees, and very much so on forest trees, and especially on Gooseberry bushes. Still there is so much of comparative helplessness or indifference because the use of undoubted antidotes seems to be rare. In America we learn that spraying of fruit trees with powerful insecticides has been rendered scientifically exact. Here a sprayer of any sort seems to be rarely used. Even with Gooseberry bushes it seems to be regarded as less an evil to see every leaf eaten up than to dress them once or twice with Hellebore powder. Even when the Potato fungus is rampant very few indeed trouble to give sulphate of copper and lime dressings to the foliage, although it is notorious that this compound is a wonderful antidote to the disease. This sort of negligence should not be found in large gardens, and especially in market gardens. In rural districts, where gardens are small and appliances are difficult to obtain, it seems desirable that local authorities should provide not only appliances, but also duly qualified persons to utilise them at moderate charges. The long-continued drought which at present is obnoxious to fungoid attacks seems to be breeding insect life wholesale.—A. D.

#### MUTILATING FRUIT TREES.

In some gardens, or some employers seem to think, a tidy appearance of paramount importance, but this may easily be overdone. By all means keep weeds under and also remove anything of a rubbishy character, but do not extend the craze for neatness to the fruit trees. It must not be thought that I would let these take their chance or grow wildly. They must be attended to in due course, though not to the extent of making all as trim as possible. Wall trees ought certainly to be summer-pruned and have all their leading shoots laid in straightly, otherwise they will become crooked to the extent of breaking when the attempt is made to straighten them next winter. Quite recently I visited an enclosed garden the walls of which were well furnished with fruit trees. Evidently enough these had been properly treated in the past and capital crops of fruit were set on most of the trees. This season a change of gardeners has been made, and the owner of the place thought the opportunity a good one for carrying out his own ideas as to how these trees should be summer-pruned. All the lateral growths on all the Plums, Apricots and Pears have been as closely shortened back as they ought really to have been next winter, and in the cases of the two first named there appears to be more fruit hanging than there are leaves on the trees. Such an wholesale removal of growth must have had a most injurious effect upon the trees. Nothing short of a very severe thinning out of the fruit will prevent the rest from being of second-rate quality; whereas had the stopping been properly done there would have been grand crops of fruit. Pruning to the second small leaf, or even to the first full-sized leaf, would inevitably cause the whole of the buds at the axils of these few leaves to push into growth this summer, and, in

fact, they were already doing so when I saw them. The bad effects, therefore, of this severe pruning will be apparent for the next two or three years, so many leafy growths forming where there ought to have been fruit spurs or buds. Lateral growths on sweet Cherries, Plums, Apricots and Pears may now be stopped at the fifth leaf, and any subsequent breaks from these be pinched back to the first leaf, this having the effect of diverting the sap to quarters where it is most needed and to plump up the back buds or those that it is desirous should develop into fruiting spurs or buds. Trees thus treated will not present an untidy appearance, especially if the leading growths are neatly fastened back to the walls, wires, or trellises, as the case may be. None but amateurs need be told that Peaches and Morello Cherries are most freely produced by well ripened wood of the previous year's growth, and the aim, therefore, should be to lay in a sprinkling of well-placed shoots all over the trees. Avoid over-doing this, as it is of importance that plenty of sunshine or daylight reach not merely the wood, but also the fruit, neither maturing properly if smothered up by leaves. Bush and pyramid fruit on dwarfing stocks grown in the open are in many instances very closely summer-pruned, and when this treatment is accompanied by annual or biennial winter lifting and root pruning there are usually plenty of fruit-buds every season. Those, however, who prefer to have larger, more naturally grown trees and heavier crops of fruit should not be too particular as to a neat appearance just now, and ought especially to avoid the form of mutilation alluded to at the commencement of these notes. It cannot be too often pointed out that the harder a naturally vigorous tree is pruned the more it will grow and the less likely will it be to crop freely. Root-pruning carried out piecemeal, one half being done one autumn and the other half a year later, will usually prove a good correction of grossness and unproductiveness, but we cannot be always root-pruning, and the very simple plan of leaving a good sprinkling of unpruned wood all over a vigorous tree will be nearly or quite as certain to have the effect of making a hitherto unproductive tree profitable enough. The first step towards this desirable end should be taken now or during the next month. Where the trees are at all crowded, thin out the young shoots freely, treating them much as advised in the case of laterals on wall trees, but many of the best placed growths should be left intact with a view to also leaving them unpruned next winter. This thinning out or shortening of much of the lateral growth on bush and pyramid trees will favour the ripening of the fruit, and the wood will also be better matured than would have been the case had no pruning been done. Treat espalier-trained trees and cordons similarly to wall trees, avoiding very close pruning.

W. I.

#### NATURE VERSUS ART.

ALTHOUGH stiffness and formality have of late years in a great measure disappeared from the flower garden, thanks chiefly to the persistent preaching of the apostles of Nature *v.* Art, one is often discouraged by chancing upon gardens, some of them large, some but a yard or two in extent, upon which evident and loving labour has been expended, with a result that makes the heart of the lover of Nature sick within him. Who does not know the flint or clinker erections, fashioned with infinite, but fiendish ingenuity, of some railway or coastguard stations? Once, indeed, at one of the former I saw a spar and clinker locomotive that must have taken months to complete. These receptacles generally contain a few Wall-flowers, Antirrhinums, or Marigolds, flowers that with their natural setting of brown or red earth or grass verge have a simple charm that they are effectually bereft of by their blatant caskets. To such gardeners, however, a sense of delicacy makes it difficult to speak one's thoughts. I always find when it comes to the point that I am

too much of a coward to condemn to the proprietor what to him is evidently such a source of pride, and end by leaving him to worship the goddess Flora after the manner of his mistaken sect, which, alas! is not to be met with only in the small plot of the working man, for in many a large garden the time-honoured motto *ars est celare artem* is glaringly ignored.

I have in my mind a public garden which might be very beautiful; even with all the sins of commission that have been perpetrated within its borders it is still beautiful. The first impression forced upon the stranger on entering is that the gardener's chief aim is to impress upon the public's notice the grandmotherly care that he takes of his charges. Nothing is allowed to grow 6 inches high without a stick and a tie. Torture at the stake is apparent on every side. During the last summer bushy Fuchsias were planted in quantity and their shoots tied to yellow Bamboo canes, some of the specimens being fixed up with as many as twenty; in fact, the poor plants seemed always of secondary importance to the conspicuous sticks that spread them out so stiltily. A bed of giant Sunflowers had inch-square stakes over 6 feet in length driven into the ground beside each plant before the latter were 2 feet above the soil; consequently, until the flowers were produced and growth completed, the stakes were the chief feature of the plot, and some of the plants not growing over 4 feet high never attained to more than two-thirds of the height of their respective supports. The most striking error, however, in the matter of staking in this garden occurred in the case of a flowering Aloe (*Agave americana*). I noticed the flower-spike just as it protruded from the huge serrated leaves: so evidently had the ever-watchful staker, for a deep excavation was being commenced at a distance of about 3 feet, and on the next occasion of my passing a gigantic mast about 20 feet in height, like an emerald-green scaffolding pole, towered over the abashed succulent. As the spike, far slenderer than its bulky wooden companion, grew it was securely fastened at intervals to the pole, which was eventually shortened to about 12 feet, the height of the Aloe's flower-spike. Now if support had been necessary in this case, it could have been easily given in a way that would have been almost unnoticeable; but as bad gales do not occur during the English summer, and as the Aloe's candelabra wavered in their thousands many a bitter gale in their native habitats without being levelled to the ground, the inference is that the disfigurement was entirely gratuitous. It spoilt the quaint effect of the Aloe's inflorescence and was merely a monument of misjudgment.

On the largest piece of turf in the garden of which I write the name of the town is cut out in letter beds, which are planted with *Pyrethrum aureum*. It is difficult to believe that any educated person could find subject for commendation in the atrocities I have described, yet so depraved, or rather I should say so unenlightened, are the tastes of many, that a section of the public is prouder of all this misdirected zeal than of the many beautiful objects and effects that the garden still affords. S. W. F.

**A Brier hedge.**—Between the flower garden a hedge of Briers extends that is now an object of exceeding beauty. By the gate are two large bushes of Sweet Brier, which on damp evenings distil their fragrance lavishly. Then come the Austrian Yellow and Copper, Harrisoni and the Persian Yellow, while the hedge ends with a large bush of the white Scotch Brier. All of these Briers, with the exception of the first named, are now in flower. The effect of long sprays of the Copper and Yellow Austrians, studded with resplendent orange-scarlet and bright gold single flowers, hanging down to the ground, while the top of the hedge is crowned with the double blooms of Harrisoni and Persian Yellow, is better imagined than described. In the brilliant sunlight of the past week the spectacle has been simply gorgeous, and few that have witnessed it but have been

struck by the vivid colouring. The ground where the Briers are planted is poor and shallow, but being left to themselves and untouched by the pruning-knife, they have formed a very fair hedge, as well as at this period of the year a very entrancing picture.—S. W. F.

## THE WEEK'S WORK.

### HARDY FRUITS.

**STRAWBERRIES.**—Those who mulched early will this season be well rewarded by the size of fruit on light soils, the mulch having greatly assisted in swelling up the fruits. At the time these notes are penned we have not had any rain to benefit the roots of these plants, and the watering recommended previously will have done much good. In watering saturate the plants say once a week in preference to dribbles, my plan being to give each root well furnished with fruit from two to three gallons. The mulch, being given as it comes from the stables, requires a certain amount of rain to cleanse and bleach the long litter, so that the watering will cleanse as well as give nourishment if applied freely. Feeding the mid-season and later plants well will repay, especially if clear water can be given afterwards, but do not pour liquid manure or fertilisers of any kind over the fruit. In all cases when liquid manures are given it should be at the root, and in the evening or in chilly weather.

**PROTECTING THE FRUIT, &c.**—This will claim first attention, especially in old gardens, as the larger birds are most troublesome. It is not enough to merely lay a single net over the plants, as the birds settle on the nets and disfigure most of the large fruits; a few supports in the way of pea stakes or pegs will prevent injury. Those who have large breadths where netting is out of the question often employ boys to scare the birds, but it is necessary to do this early in the day, quite by sunrise. To preserve the fruits from the soil I do not think there is anything to equal clean straw. Short Grass from the mowing machine is at times used, but it is not nice in wet weather; it adheres to the fruit, becomes mouldy, and does more harm than good. Tan after the heat is spent and in a clean state is superior; it also retains the moisture in dry seasons, and is a splendid preventive of slugs in wet seasons, an important point, as slugs do much damage. Of late years various contrivances have been introduced. Wire guards answer well for large plants in wet seasons, as the fruits, being raised, get more light and air, and with only small quantities of fruit, tiles, slates, or other flat surfaces are well adapted for placing under large clusters. Previous to netting or protecting of any kind, watering should be done and the surface between the rows made clean. Late kinds, such as British Queen, Lord Sufield, Latest of All, Oxonian, and others well repay for a little extra attention, as they come in when the glut is past, and I fear this season will be a very short one owing to drought and heat. It is well to mulch these more liberally, using shorter material and water well to settle and cleanse the mulch. If necessary to get large, late fruits, thin the trusses of the heavier kinds, as Latest of All and Oxonian bear very freely. Those who have north borders for their late crops will be better supplied, as they are cooler in such seasons, and the advantage of growing young plants is, they are better able to stand seasons of drought.

**LAYERING YOUNG PLANTS.**—The season is at hand for layering, and I have always found the earlier young plants can be obtained and got into the fruiting pots or growing quarters the better; and for early runners it is advisable to have a special plantation of plants not allowed to fruit. There are various means adopted to root the plants. Good results are obtained by layering direct into the fruiting pots, using 5-inch pots for early forcing; others layer into 3-inch pots and pot on when rooted—an excellent plan—as there is no water-logging in wet seasons and firm potting

—a great necessity—can be ensured. The old method of layering into pieces of cut turf has several advantages and is admirably adapted for planting, the roots so soon go into the new turf and are planted very quickly with less trouble. The turves should be plunged in the space between the plants and well watered. To get large quantities of rooted runners from young plants just cleared of their fruits it is a good plan to place some rich soil between every alternate row of plants and peg the runners into it. These make good strong fruiting plants for next season, and if the runners are layered as advised, by leaving every other row there is room to water and work between the plants; but it is necessary to make the runners firm to obtain strong roots.

**YOUNG STRAWBERRY BEDS.**—The value of yearling plants is now so well known it is almost useless to point out their superiority over older ones. A few varieties may be excepted, but they are very limited. Those who require very early fruits of the best quality would do well to rely upon young plants raised at this season for planting early in July, and such plants in favourable seasons will give a heavy crop in eleven months from time of planting. For early fruits I have found none to equal Noble, on a sloping south or south-west border the fruits are very early and fine. Royal Sovereign is equally early, of superior flavour, and doubtless when more plentiful will supersede Noble, but the latter in poor soils will thrive where others fail. Latest of All is very fine grown on young plants for late use. Ground just cleared of green crops such as Cabbage may be prepared for the young plants, digging deeply, giving plenty of manure, and by doing the work now it will be ready to plant when the runners are rooted.

**RASPBERRIES.**—These were much injured last winter, especially some of the weaker growers, but the newer varieties, like Superlative, are more hardy. It is best to reduce the shoots of these weak growers, so as to get as strong fruiting canes as possible for next season, three to five at a stool being ample. Suckers are more numerous than usual this season, owing to there being less top growth to support, and there should be no time lost in getting rid of the great majority of these. The strong growers require more room, as if crowded the fruits are small. The rows between the plants should be hoed, and the useless sucker growths at the stools pulled out by hand. Raspberries require both food and moisture on light soils, and few crops pay better for liberal supplies of liquid manure; the plants being surface rooters, they will take large supplies. The autumn-planted roots in many cases did not survive the severe winter, but those which are pushing up new growths from the base should get every encouragement by mulching, keeping the ground clean and restriction to the strongest growths, three or even one being ample to get good canes. Autumn fruiters cut down hard to produce new growths or fruiting wood should also be thinned to get fine fruits, giving food as advised; they will then fruit well into October and in quantity, bearing all up the growths if these are given plenty of room to develop.

**GOOSEBERRIES.**—In many gardens the caterpillar at this season plays havoc with the leaves, and it is impossible to arrest the destruction if not taken in hand vigorously, the difficulty being if any insecticide is used which adheres to the fruit it is not pleasant to use the fruit afterwards, and when fully ripe they cannot well be cleansed. I have found nothing to equal hellebore powder dusted on the trees when damp and the soil under the trees coated with fresh lime. Syringing with quassia extract is also excellent in dry seasons, using hellebore in damp weather. Change of quarters will also do much good, lifting in autumn with a ball and giving plenty of good soil and manures. The Gooseberry also suffers in dry seasons from red spider. A mulch of manure will do much good and prevent spider getting ahead, as the mulch retains moisture and assists in keeping the surface roots cool. Syringing with water and sulphur mixed will kill the pests,

and the sulphur is readily washed from the berries.

CURRENTS are bearing freely, and may with advantage be lightened of any useless wood, such as crowded lateral growth: this may be spurred back to within four joints or leaves from the base, which will give the leading shoots more room and the fruits will colour better. Bush fruit trees derive great benefit by removal of useless shoots. Sucker growth should never be allowed, and young trees for planting later should be kept in shape by pruning occasionally, keeping them to one leg or stem, as the crop is more readily gathered.

G. WYTHES.

### KITCHEN GARDEN.

**CARDOONS.**—The main batch, if sown some time ago, will now be ready for planting into the trenches—that is to say, if hardening off has been attended to. Cardoons require a wider trench than Celery and quite as rich a root-run. Give plenty of room between each plant—2½ feet is a good distance where ground is plentiful; where scarce, 2 feet will do. Cardoons must never be allowed to feel the want of water, a weekly soaking if the weather is dry not being any too much. When once in vigorous growth liquid manure may be given once in three weeks. If plenty of space is allowed between the trenches—say 5 or 6 feet—sufficient soil will then be had for earthing, and the ridges may now be used for growing Lettuce and other quick-maturing crops. The best way is not to earth up the plants until fully grown, when hay-bands should be closely wound round the stems to keep them together and to prevent the soil from getting into the centres. In severe weather they must be lifted and protected; they then form a useful and generally much appreciated dish. Those who have not yet sown may do so in heat in small pots and finally plant the seedlings into trenches in a sunny, open position. Small useful plants may then be secured by November. The Large Spanish and Paris Market are the best varieties for general use.

**LATE CELERY.**—Those who grow Celery for a late supply must now attend to the young plants. As soon as they will bear handling prick them out in some sheltered nook in rich soil placed on a hard ash bottom, the same being surrounded with bricks turned on edge. A few Yew or Laurel boughs placed here and there will answer a double purpose—shading from hot sun and also from parching winds until well established. Where very late Celery can be accommodated it often proves more serviceable than the main crop, especially should the season turn out wet and rot set in. The late, being smaller, is likewise harder and more rot-proof. Standard Bearer and Leicester Red are two capital sorts for late work and of good quality.

**SOWING LATE PEAS.**—It is quite time now in the majority of gardens to sow Peas for the latest supply—that is, during September and October. A good sunny, open position should, if possible, be given, as mildew often affects these late lots. Ne Plus Ultra, British Queen, Walker's Perpetual Bearer, and Sturdy are all good for the purpose, and will form a succession if sown in equal quantities. Plenty of room between the rows is imperative, as, unless abundance of light and sun is admitted, the chances are that failure of the crop will ensue. Thick sowings are also ruinous, encouraging mildew and other troubles. When well up give a heavy mulch of good manure and plenty of water, as these late, tall-growing, robust sorts soon rob the soil of its moisture. Sometimes good pickings may be obtained from sowings made towards the end of the month of such early sorts as Chelsea Gem and Selected Early.

**PLANTING WINTER STUFF.**—Now that genial rains have fallen, no time should be lost in getting out more rows of successional winter vegetables. We have this week put out Veitch's Model and Cooling's Matchless Broccoli, the former unsurpassed for late spring use; the latter, a valuable hardy variety, coming into use in March and April. I do not approve of planting these sub-

jects between rows of Potatoes, unless the latter are extra wide apart, as the haulm invariably smothered and spoils the Broccoli, and even if they survive they are leggy and weak, and quite unfitted to stand a severe winter. Amongst short-topped, earlier Potatoes, however, that can be bent over so as to admit air and light to the plants, both Broccoli and Kale may be planted. Get out also both the tall and dwarf forms of Scotch Kales, also Asparagus and Cottager's Kale, the former about the most useful of all greens, it being so extremely hardy and such a continuous grower, the flavour also approaching that of Asparagus, as its name implies. Savoys also, more Walcheren Cauliflower and Cabbages to heart in in autumn, may be planted where ground is available. Late Brussels Sprouts which were

*Juglans Sieboldi.* From a photograph sent by Mr. L. Burbank, Santa Rosa, California.

pricked out into beds some time ago may now be got out into their permanent quarters. Where such very late Broccoli as Late Queen and Methven's June are grown, the sooner the plants are put out the better, giving them firm ground from which some fairly impoverishing crop has been cleared. Cauliflowers now turning in should be gone over daily and some leaves bent down over any forward heads to retard them, the sun and light soon discolouring them at this season. Cauliflowers may be kept for ten days or so if wanted for exhibition by lifting the plants with as much soil as possible and placing them in a tub of water in a cool cellar or fruit room, the water just covering the balls.

**SALADING.**—At this advanced date more care is requisite in providing a regular supply of green crisp subjects for the salad bowl. Position is a great point, and for Mustard and Cress, Radishes, and Lettuces a cool east or even a north border answers best. It is a capital plan to cover the seed beds lightly with some litter or garden mats until the seed has germinated. Perhaps the best method of growing Lettuces from now till the autumn is by sowing in drills and thinning out the seedlings to the proper distances. This saves labour, enables the plants to arrive more quickly at maturity, and lessens the liability to run to seed. A good Lettuce for sowing now is Veitch's Perfect Gem, it being of excellent quality, and Corn Salad or Lamb's Lettuce is not so generally grown as it deserves to be. During November and also in the spring months when good Lettuce and Endive are sometimes not over plentiful, Corn Salad comes in most useful and makes a desirable change. Seed sown now will produce plants for use in November, and a sowing a month hence is best for the spring supply. Drills are best on good rich, deep soil, allowing plenty of room both between the rows and the individual plants. Corn Salad needs a little protection in severe weather, dry litter of the common Bracken answers the purpose well.

**HERB BEDS.**—These should now be thoroughly cleansed from weeds and well watered if necessary, or many blanks will occur amongst the more tender transplanted sorts. Where these were sown in the open beds, thinning out must not be neglected, as Salsafy, Marjoram, and similar subjects soon turn yellow and decline if left too thick. Thyme and Sage planted this season will be much benefited by a good mulch of old Mushroom manure or even rough leaf-mould.

J. CRAWFORD.

### TREES AND SHRUBS.

#### JUGLANS SIEBOLDI.

THE remarkable Walnut, whose curious raceme of Nuts is shown in the accompanying illustration, is the chief representative of the genus *Juglans* in Japan. It is abundant in the northern island of Yezo and is also found in the more southern divisions of the empire, but is there confined to mountain districts. There are not, so far as I am aware, any trees of fruiting size in this country, although several young ones are in the arboretum nursery at Kew. According to Professor Sargent, however, it ripens fruit not only in such favoured States as California, but also in much colder districts where even the common Walnut (*J. regia*) will not succeed. On the plants at Kew the pinnate leaves consist of from seven to eleven leaflets, these being slightly pubescent on both surfaces and having shallow, irregular teeth on the margins. Professor Sargent, describing it as seen in a wild state in Japan, says it is a wide-branched tree rarely exceeding 50 feet in height, with pale, furrowed bark. The Nuts, whose characteristic arrangement is well shown in the picture, are about 1½ inches long, with a diameter one-third less, the kernel resembling that of the common Walnut in flavour. Of its possible value in Great Britain little can be said as yet, except that it is perfectly hardy. It is said to be inferior to the Black Walnut (*J. nigra*) as an ornamental tree, and the climate of even the more northerly portions of the United States is so much better suited to the deciduous trees and shrubs of Japan, that its fruiting there can only be taken as evidence of the probability of a similar success here. According to Dippel, this tree is the same as those known in gardens as *J. macrophylla* and *J. ailanthifolia*.

The only other *Juglans* found in Japan in a truly wild state is *J. cordiformis*. It is in cultivation at Kew, and somewhat resembles *J. Sieboldi* in foliage. At present the former is distinguished by the more numerous and somewhat smaller leaflets and by a more marked pubescence on the leaf surfaces than occurs on those of Siebold's Walnut. The Nuts are flattened, long-pointed and more or less heart-shaped.

W. J. B.

#### CEDARS OF LEBANON AT HOME.

A LONG-FEELT wish to see this noble tree on its native hills has at last been gratified, and our impressions may have some interest for the many who admire this tree. It may be as well at once to clear the ground by saying that the division of this Cedar into two species is not one that should stand, as if there is any difference worth noting it is that of a mere variety only. Nor does it inhabit Lebanon only; that is but one station, and, we believe, a small one. There are more important habitats in Asia Minor, where this tree is widely distributed, and there are forests of it in Algeria, a visit to one of which we are now concerned with.

It is a pretty long tramp on foot or mule from any tolerably decent resting-place to Mount Babor, but once there the lover of the Cedar is at once impressed by the many aspects in life and death of the tree—the *death note* being, unhappily, too impressive, owing to the work of Arabs, fires, lightning, browsing animals, and other enemies. In some parts, indeed, with white barkless, dead trees, the mountain looked a tree cemetery. Clearly for ages it has been no one's business to look after the forest, and though it is not near any place of importance where the wood would be of much use, savage destruction has been the rule for many years. In Bruce or some other traveller we read of Africans who had a horrible way of taking a steak out of a living animal; and in this mountain the natives take the plank out of the living tree. Over much of the forest almost all the fine trees had been treated in this way by men who, not caring to cut the whole tree, cut into its side, and, taking out large planks, leave it to get on as best it may. These planks are dressed on the spot, a fine heap of chips remaining about, which anyone wanting a fire lights, and as likely as not burns part of the great stem. Small wonder if in the face of such doings many of the burnt trees are dead. No tree escapes disfigurement. Young and graceful trees that might soon take the place of the dead are broken off for sticks, and the second or third growths are treated in the same way. Continued mutilation of this kind of course leads to deformities, so that it is perhaps not fair to assume that the tree is here anywhere in a natural state as to its form, but the result is often beautiful nevertheless.

From a picturesque point of view no tree effects we have ever seen were better, and it would be impossible to give any idea of the variety of form seen in every degree of size, beginning with scrubby trees on the shaly sides of the mountain. It is probable that

the cutting of the points of the young trees repeatedly may have led to the wondrous variety of form we saw, but in any case it was very beautiful. Many of the smaller and medium-sized trees were not of one stem, as we expect to see in a Cedar, but many-stemmed and broken even as one rarely sees a Yew, the main branches of others leaning to the ground in infinite variety of contortion, the whole of the trees on the exposed sea-side being shorn by the north-east wind. The trees on the flank of the mountain are handier for the natives to get at and were probably oftener cut. In any case it is only on the top and upper slopes of the mountain that the stately Cedar is seen, sometimes very large and fine in form with great stems, though even among these big trees there is more variety of form than might be expected.

The best trees were on a sharp slope not so easy to swing an axe on, and protected by the crest of the mountain from the sea winds, and these trees were very beautiful and large, their plummy crests lovely when seen from ground above them. The boles of the trees were as large, some larger than the oldest and finest trees we have seen in England, but not so high as some. On the side most exposed to sea winds many trees grew on sharp slopes of broken shale without any visible trace of soil, though these were not, naturally, among the finest trees.

This may well suggest to planters that it would be well to be not so very particular about planting this tree on the best ground, and best prepared only, as is so often done with us. For the sake of variety, if for no other reason, it would be as well to try groups on such soil as the Scotch Fir thrives in. But there is more reason than that of variety for the plan, as it is pretty certain that very rich soils lead to quick and sappy growth and to a shorter life of the tree. All lovers of the tree who have the pleasure of planting it should try it in other ways than the isolated way usual in pleasure grounds, where the tree has to meet all the winds without any aid from neighbours while overlaid with heavy tree-like branches, which catch the snow in quantities enough to break them down. We do not say trees of this form are not beautiful, but they are but one form of the beauty this tree may give: it should often be planted in groups, and also closer among ordinary trees, where a noble Evergreen for game or other reasons is desired; with other vigorous forest trees it grows erect, with a taller bole. We mean here that it should be planted and grow up with young forest trees.

The glamour of the name of this tree leads to its price being kept up pretty high, which does not matter so much if we only plant one now and then, but in planting in quantity it is a more serious matter, and as there is abundance of good seed in the natural woods of Cedar both in N. Africa and Asia Minor, it ought to be obtainable almost as easily as any hardy Pine. And we think it better worth growing in our woods than some of

the Pines we plant of doubtful value, as the Spruce in many parts of the south of England—the Spruce being such a poor timber too. The trees of the Cedar we saw cut into the heart by the natives were in all cases clean and sound to the core, the wood pretty in colour and yielding a grateful odour. We cannot judge the value of Cedar wood from its growth in our country, where in over-rich soil the growth is often too rapid for good, lasting timber; but it is of higher value than that of Scotch Spruce or Silver as we grow them. There are the remains of a log in the Museum at Carthage said to be about 2000 years old, so there may be available evidence of the value of the native-grown Cedar of Lebanon. Then, again, every year Conifers are planted that have not the hardness of the Cedar of Lebanon on its cold mountain crests, where the snow is often yards deep in winter, and where it lay deep in many places on the day we saw the trees—May 3. These conditions are not so diverse from those of our own country as those of the climate of California, from whence many popular Conifers come. On the mountain, too, we saw some of our native wild flowers among those of the mountains of Algeria; but more striking still is that among the Cedars are many trees of our English Yew, healthy, but mutilated even more than the young Cedars, every branch being cut back repeatedly to supply probably some parts of the wooden ploughs or tool-handles. On lower mountains in the region near our common Hawthorn was in fresh bloom on the same day. But besides these facts we have the evidence of the old trees in many of our country seats; in some—as at Goodwood and Pains Hill—where the trees are more than usually effective from their number as well as size and stature. So we think it is time the Cedar was no longer valued as a pleasure-ground tree only, and that it should be freely grown here and there in our woods in groups, and also occasionally as a wood by itself.

As to the destruction of the trees on Mount Babor, it may be hoped it will not always be a discredit to the forest department of Algeria, and it should not be a great difficulty to exclude browsing animals and the ruthless destroyers of the fine trees, though it is an outlying situation. The interest of the tree is great, and the mountain commands a vast sea of broken landscape reaching into infinite distance in every direction, so that even if the timber has little value commercially, this home of the Cedar well deserves the care of the State.—*Field*.

***Acanthopanax ricin folium*.**—In many catalogues this is found under the name of *Aralia Maximowiczii*, but its true place is in the genus *Acanthopanax*, of which about half a dozen species are found in China and Japan. It is, according to Dr. Sargent, the largest araliaceous plant of Japan, for the tree will sometimes attain a height of 80 feet, with a tall, straight trunk 4 feet or 5 feet in diameter, covered with very thick, dark, deeply furrowed bark, and immense limbs that stand out from the trunk at right angles like those of an old pasture Oak. In this country it is, however, of comparatively recent introduction,

but, from the vigorous style of growth, it bids fair to soon attain a considerable size. As a young plant is has a decidedly sub-tropical aspect, the sturdy stem being as straight as a gun barrel, and freely furnished with large spines on the upper portion. The leaves, which are borne on very long, deep-coloured stalks, are palmate, five to seven-lobed, and of a dark shining green on the upper surface, but lighter beneath. It is perfectly hardy, for though in the winter it has a decided dead-stick appearance, on the return of spring the new foliage pushes forth in all its beauty. It succeeds best in a rather deep soil that is not parched up at any time. A bed planted with young, vigorous specimens at a sufficient distance apart, to allow for the full development of the handsome leaves, will form a very striking feature, quite equal to that presented by many sub-tropical subjects that need a hothouse during the greater part of the year.—T.

**Pernettyas.**—In some districts these have suffered a good deal from the late severe winter, but where they have escaped they are as usual flowering freely. Much as we have heard of the ornamental features of the different *Pernettyas* owing to the beauty of their berries during the winter months, a few words of praise may be spared them as flowering shrubs, for the pure white wax-like blossoms are borne in great profusion and present a very pretty appearance, nestling, as they do, among the small dark green leaves. Being of a stout texture, these flowers remain fresh a considerable time, and they are decidedly useful in a cut state. Though by carrying out a process of selection great changes have been effected in the berries, the flowers of all remain just about the same.—T.

**Dimorphanthus mandshuricus.**—This name is generally applied to what is apparently but a form of the North American *Aralia spinosa*, but in any case a vigorous specimen is highly ornamental by reason of its huge compound leaves and from its blossoms, which are borne towards the end of the summer or early in the autumn. It forms a stout, erect stem, the younger portion of which is furnished with numerous spines. The stem will reach a height of 10 feet to 12 feet or more, and at the flowering season is terminated by a large branching panicle of whitish blossoms. It is a plant that pushes up shoots from the base in considerable numbers, so that an established specimen makes a large mass or clump, consisting of numerous stems, which, being each clothed with the very large compound leaves during the summer, cover a considerable space, and as autumn approaches and the stoutest shoots bear aloft their large panicles of blossoms, it is then a very striking feature. It is thoroughly hardy and easily increased by root cuttings, as if a specimen is transplanted and some of the roots are allowed to remain in the soil, young plants will often crop up the following season.—H. P.

## STOVE AND GREENHOUSE.

### THE EUPATORIUMS.

THIS genus is closely allied to that of the *Ageratum*, well known as a useful bedding plant, also to the *Hebeclinium*, another very serviceable decorative greenhouse subject. Those that are usually cultivated under the generic name of *Eupatorium* comprise but a few varieties. These are very useful where flowers in quantity are wanted either in a cut state or upon the plants during the winter or early spring months. They are of specially good service for large conservatories or greenhouses where it is impossible to grow many of the hard-wooded plants with that success one desires to see. Being plants of easy culture and of rapid growth, it is not a difficult matter to grow on a stock of young plants every year,

keeping the best only of the previous season's propagation, so as to have some at least of larger size if needed.

The species which forms the subject of the accompanying illustration is, perhaps, the most useful of any, as it flowers during the winter months, being easily had in flower to succeed the *Chrysanthemums*. Earlier than this it is scarcely desirable to flower it, although it could be had in good condition in October if need be. I have found it to be very useful during December and January, and in order to flower it then it is better to stop the shoots during the early part of September. The other two varieties—one of which is tall and the other dwarf—to which attention might be drawn are *E. odoratum* and *E. riparium*, but these flower during the spring season when many other plants, as bulbs, &c., are in their best condition. The culture is quite easy and growth too luxuriant if the plants are overpotted or treated with stimulants before the flower-trusses are well advanced. Two or three stoppings are certainly desirable, so as to form more bushy plants.

*Eupatorium Weinmannianum.* Engraved for THE GARDEN from a photograph sent by Miss Gaisford, Offington, Worthing.

Out-of-door treatment will answer well up to the middle of September from early in May. When housed, the ordinary temperature of a greenhouse will suit them; light, however, is necessary, so as to keep the growth as compact as possible. Propagation is best attended to about March, the cuttings striking freely enough in a little warmth. Amateur growers, instead of attempting to grow the Indian *Azaleas*, not always easily managed in such cases, would do well to try their hands on a few *Eupatoriums* instead. *E. Weinmannianum* is a native of South America. GROWER.

**Clematis indivisa and Niphetos Rose.**—Recently when at Bashford Nursery I observed these growing in the same house with the best results. *Niphetos Rose* was planted out in narrow beds near the front lights and allowed to grow up two-thirds of the roof. At both ends were planted *Clematis indivisa*, which covers all the space under the centre of the house. It comes into bloom early in the year and the bunches of white flowers sell well early in the season. The

heat that is given to the *Clematis* just suits the *Rose*, as it helps to bring on the blooms early. Nothing could be finer than were these *Roses*, and I was told by the grower that he obtained three crops from these plants every year.—DORSET.

### K. EMPFERIA KIRKI.

THIS is one of the many *Gingerworts* remarkable for the beauty of their blossoms, which, though they do not last long, are as a rule produced in considerable numbers from the one scape, so that in the case of vigorous examples a display will often be kept up a couple of months or thereabouts at this season. This *Kampferia* first flowered at Kew in 1881 under the name of *Cienkowskia Kirki*, and as such a coloured plate of it was given in THE GARDEN of November 19 of that year. Since that time, however, it has been by some botanical authorities relegated to the genus *Kampferia*, though it is still frequently met with as *Cienkowskia*. It forms, like many other of its class, a thick fleshy rootstock, from whence are pushed up Plantain-like leaves about a foot long and thin in texture. The flower-scape rises to a height of a foot or so, and the individual blooms are rose-coloured, with a golden blotch at the base of the lip. In size, colour, and general appearance they remind one a good deal of the flowers of *Miltonia vexillaria*. It is a native of the Zanzibar region, and forms a very pretty and useful subject for the stove. In such a structure it is of very easy culture, as it passes through the winter in a dormant state; then, on the return of spring, it should be shaken clear of the old soil and repotted, when if placed under conditions favourable to growth the leaves will soon be pushed up and followed quickly by the flower-spikes. A soil composed of loam, leaf mould, and well-decayed manure will suit this *Kampferia* perfectly. As it passes the winter in a dormant state, it must at that season be kept slightly moist—in fact, much the same treatment as a *Caladium* should be given it.

A second species, *K. rotunda*, was figured in THE GARDEN, August 18, 1888. The flowers of this are developed just as the leaves begin to push up. They are less regular in outline than those of *K. Kirki*, and the colours are altogether different, the lower petals being bright violet-purple, veined at the base with white, and the upper petals are entirely white. They are also very agreeably scented. This species, as a rule, flowers about April, and the foliage is now decidedly ornamental, being of a dark green tint marked with grey and purplish on the under sides. Regarded from a foliage point of view alone, *K. Gilberti* has much to recommend it. The style of growth is somewhat after the manner of the smaller *Funkias*, as it forms a dense tuft of bright green leaves freely marked with pure white. A large pan of this species forms a very pretty object for many months, or neat little specimens may be grown in comparatively small pots, and they are then extremely useful for decorating. They are all plants of easy culture, and the two last named species will succeed in a structure which is kept at a rather lower temperature than that necessary for *K. Kirki*.

H. P.

**Anthurium crystallinum.**—Although common and cheap, this *Anthurium* is one of the most beautiful fine-leaved plants in cultivation, and if it happened to be a novelty of the present day we should doubtless have it greatly praised. The large heart-shaped leaves are of a deep rich velvety green, while the midrib and principal veins are marked out in silvery whiteness clear and distinct from the rest of the leaf. The young leaves are of a pale brownish green, suffused with violet, which varies greatly according to the age of the leaf and the point from which it is viewed, the violet lustre depending greatly upon the

direction of the rays of light. All plants are, however, not of equal merit in the colouring of their leaves, some having the silvery bands broader and more clearly defined than others. In common with most of its class, this Anthurium is of easy culture, for it delights in a mixture of rough peat and Sphagnum, to which may be added a little fibrous loam, at the fancy of the cultivator. A good amount of sand should be mixed in the compost. The plant requires a moist portion of the stove, and as a good deal of its beauty is lost if the leaves are disfigured in any way, care should be taken to remove insect pests without bruising the foliage.—H. P.

**A triple Arum.**—I do not know if you are tired of monstrosities among Arums, but I send another one. It has three perfect spathes with one spadix only, and they are quite uniform in size and in arrangement on the single stem. Last year I sent you one that I thought far more curious than this, as the flower-stem was jointed and produced from the joint a perfect albino leaf, surmounted with a spathe of the ordinary form. I was then and am still anxious to know if a similar case has occurred, as I do not remember having seen a note of such a freak.—J. C. TALLACK.

#### GREENHOUSE RHODODENDRONS.

Now that the various Himalayan Rhododendrons and the numerous hybrids raised therefrom are, with the exception of *R. calophyllum*, all past their flowering season, the members of the Javan or tube-flowered group, whose period of blooming is limited to no particular part of the year, are in many cases flowering freely, that is to say, in the intermittent manner common to most of them, for they are continually pushing forth new shoots, which when mature are terminated by a flower bud that soon expands. Though these Rhododendrons are usually spoken of as greenhouse varieties, it is now generally recognised that for a greater part of the year a temperature above that of an ordinary greenhouse is essential to their well-doing, but during the summer months they do not require any fire heat. They are greatly benefited by a liberal use of the syringe, but if the atmosphere is too stagnant, mildew will sometimes attack the weaker varieties and cause a good deal of trouble. There is a great amount of difference in the constitution of the varieties of this class of Rhododendrons, one of the most robust being the oldest of all, Princess Royal, and as a rule the high coloured forms are weaker in growth than the pink ones. As their flowering season is limited to no particular period of the year, it will be fully understood that when repotting is to be carried out it cannot be done all at once, as in the case of the Himalayan hybrids, which all flower at much the same time, then make their fresh growth, and do not bloom again till another year comes round. The Javan varieties, however, behave in a totally different fashion, and as it would not do to repot a specimen just coming into flower, the operation must be left over till the flowers have dropped. The present, however, is a very suitable period for repotting those that require it and that are at the same time free of flowers or advanced buds. A good compost for this class of plants is fibrous peat, with a liberal amount of rough silver sand, and some nodules of charcoal mixed with the soil. This charcoal is especially necessary in the case of large specimens, as it is very essential to keep the soil sweet and fresh, for the delicate hair-like roots are very sensitive. Owing to this the draining of the pots should be very carefully done, for in many cases the plants will stand for years without repotting: hence it is so necessary to have everything clean and sweet. The soil must, as in the case of most hard-wooded plants, be pressed down firmly. It should also be borne in mind that Rhododendrons of this class are by no means vigorous rooting subjects; hence care should be taken to guard against over-potting, as large plants can be grown in comparatively small pots. It is also a very good time of the year to propagate these Rhododendrons by means of cuttings, which are by no means difficult to root, all that is needed being to

form the cuttings of the half-ripened shoots, finish them at the base with a rather long sloping cut, and then dibble them into pots prepared for the purpose. These pots should be well drained and filled firmly with very sandy peat. Care should be taken that the soil is well pressed around the cutting, especially guarding against any cavity at the base of it. After being watered they must be placed in a close propagating case in an intermediate house temperature, and in this way they may be struck, potted into small pots, and established therein before winter. H. P.

#### THE VARIEGATED IVY-LEAVED PELARGONIUMS.

THE Ivy-leaved section of the Pelargonium family has had considerable additions made to it of recent years, but this has chiefly been in the direction of greater variety of colour and an increased number of double forms. For these we are grateful, as anything that is less void of close and formal growth than the so-called bedding Pelargoniums must be considered an acquisition. The variegated section has not, however, had that same amount of attention bestowed upon it. The few varieties that are grown do not, on the whole, appear to receive that attention they should do, more particularly when thinking of *P. elegans*, which is undoubtedly the best variety in cultivation, the leaves of which are neatly margined with clear white, whilst the flowers also are white. This kind is well adapted for hanging baskets, and grown in this way it is very attractive for conservatories or greenhouses. Another use to which this pretty Geranium (I like the old-fashioned name the best) can be put is for filling up bare spots on rockwork during the summer. For this purpose it is particularly well suited. No better place for it could be chosen if it is desired to make any considerable increase in the stock this coming autumn. In pots, again, it cannot be put to a better account than as marginal edgings to greenhouse and conservatory stages, or for bracket plants or window boxes. *P. elegans* is not of rapid growth by any means, but its progress is pretty sure and reliable; hence it should not be planted too near those plants of like character which happen to be stronger growers. As an outside edging to flower beds it is also recommended, being in many respects better than several other plants so used, which have to be constantly pinched or trimmed to keep them within limits. Another and a much older variety used to be grown which had an occasional variegation of golden blotches, that eventually toned down to a pale green. This is no loss, in my opinion. Note should, however, be made of Duke of Edinburgh, of which the growth is as free as that of the green varieties, the foliage being broadly margined with white; also of *aureum marginatum*, the variegation of which is pale yellow. The cultural details are similar to those required for the green-leaved section, too rich a soil being in no case advisable. GROWER.

**Elæocarpus cyaneus.**—In selecting plants for adorning the greenhouse or conservatory there are many desirable subjects that may be kept in health, and can be depended upon to flower year after year with but little trouble. The *Elæocarpus* in question is one of this class, while the distinct character of its blossoms is another great point in its favour. It is a native of Australia, where it attains the dimensions of a small tree, but in this country flowers are freely produced while it is still a bush; indeed, I have had little specimens in pots only 6 inches in diameter which bloomed well. It is, however, as a bush 6 feet high or more that this *Elæocarpus* is seen at its best, for the numerous twigs being then all laden

with its beautiful blossoms the entire plant forms a charming sight. The flowers are pure white and bell-shaped, their most prominent feature being the delicate manner in which the petals are fringed, reminding one somewhat of the little alpine *Soldanellas*. When a plant is at its best this lace-like fringe is sure to attract the attention of all. These blossoms are succeeded by berries, which acquire a purple hue when ripe and are then decidedly ornamental; but as the flowers are the principal feature of the plant, the fruits are by some removed as soon as possible after the flowers fade in order to devote the entire energy of the plant to the production of blossoms. A glance at a coloured plate of this *Elæocarpus* in THE GARDEN, September 1, 1883, well shows the beautifully fringed flowers. If the berries are allowed to ripen they form a ready means of propagating this *Elæocarpus*, but as plants obtained in this way do not flower so freely in a small state as those obtained from cuttings, this latter method is usually employed for their increase. Cuttings are not at all difficult to strike if treated as the general run of greenhouse plants—that is, formed of the half-ripened shoots, dibbled firmly into pots of sandy soil and kept close till rooted. Established plants may be kept in health for years without repotting; hence it is very necessary when they are potted to see that good drainage is ensured, and the compost used should be such as will remain in good condition for a long time. Not only can specimens be kept in pots or tubs, but when planted out in a prepared bed they will do well. When in pots they may after flowering be placed out of doors, as is often done with many greenhouse plants, but if small they had better be plunged, in order that the roots may be maintained in an even state of moisture.—H. P.

#### SHOW PELARGONIUMS.

It was recently stated that the fine large-flowered show and fancy Pelargoniums are being neglected, and yet they are among the most useful and attractive of greenhouse plants. Some varieties recently in flower at the Royal Nurseries, Slough, are really superb; they are good growers and very free, and with proper culture successional in blooming. One of the brightest is Turner's Fireball, which has rich deep scarlet lower petals and glossy black top ones, very fine for exhibition. Duke of Norfolk is also brilliant in colour, the top petals dark, the lower petals deep crimson-scarlet, and it has a conspicuous white throat. Prince Leopold is very bright and so effective as an exhibition variety, that it invariably finds a place in a competitive group. Excellent is well named, as the flowers are of the finest form, the lower petals light crimson with a deeper veining and dark top petals, and also very free; and Martial, rich deep crimson with maroon top petals, is also good. One of the most distinct of the large-flowering show Pelargoniums is Purpurca, the lower petals being bright purple, edged with lilac or shaded with rose, a most attractive decorative plant. In softer tints, Joe, rosy purple lower and dark purple top petals; Maid of Honour, pink, with dark blotch on the upper petals; Magnate, very fine; Mystery, rosy salmon and dark top petals, very pleasing; Ronald, and Symmetry, which is well named, in colour lilac rose, are a selection of high merit.

As the plants go out of bloom at the end of June or later, according to the time of year at which they bloom, they should be placed in a cold frame or in the open air in a somewhat sunny position to ripen the wood. Water should be gradually withheld, so that the wood may become hardened and in a condition to make cuttings. Soft, green and sappy wood does not root nearly so well as that which is harder, and if placed round the sides of pots filled with a sandy compost and kept in a cold frame and shaded, so that the soil does not dry rapidly, the cuttings soon root. When rooted they can be potted singly into medium-sized "long toms," using a compost containing leaf-mould and sand, and the plants wintered in a greenhouse. R. D.

## CHRYSANTHEMUMS.

## CULTURAL NOTES.

Now that the plants are all in the pots in which they are to flower, except perhaps the latest batch that are to give us the last crop of flowers, provision must be made for getting them into their summer quarters without delay. Usually at potting time they are stood close together in a sheltered corner until all are potted. By that time the forwardest will have become nicely established in the large pots, and will be ready to undergo the usual routine of summer management. Where several hundred plants are cultivated for the production of large blooms and a large batch for cutting from in addition to a goodly number for providing late flowers, a large space must be provided for them during their summer season. The best site should be set apart for those plants that are to produce blooms for exhibition, as plants that are immature in growth cannot produce the finest flowers. If the growth of the plants has been gross during the summer with large leaves and thick fleshy stems devoid of woody tissues at the end of September, we know that the requirements of the plants have not been all that was necessary during the growing season. Too liberal use of manure in the potting soil and loose potting may have much to do with this state of things, but an unsuitable position for growth during the summer may have even more to do with the unsatisfactory condition plants are found in at the time stated. A position sheltered from the south-west and in the full blaze of the midday sun, and as long as it can be obtained during other parts of the day, is the best that can be chosen for the plants. Here with plenty of space the growth matures as it proceeds. The best position of all is beside paths near to the water supply, where abundance of light is assured and the plants standing on boards, slates, or tiles are convenient for attention and handy to water. Provision must be made to secure the tall-growing varieties against breakage. For those that grow 10 feet high or more two wires fixed to stout posts, if the line is a long one, will be required. To these wires the stakes in the pots should be made fast. Some cultivators tie the three branches loosely to one stake thrust into the pot. It is a much better plan, however, to tie the centre branch of the three to this stake and make the remaining two fast to temporary small stakes tied to the wires. In this way all the shoots or branches are spread evenly out and given an equal amount of space, so that the leaves of one shoot do not overlie those of its neighbour. By this means the development of the leaves will be perfect and will not be nearly so liable to attacks of mildew as they are when huddled together. Where the plants are of necessity placed in parallel rows in one block, they must be so arranged that the shade thrown from one plant does not affect the next plant. Where possible under such conditions the rows should run east and west and be at least 5 feet apart. The plants should be restricted rigidly to the number of shoots allowed, which usually is three. A few cultivators confine many of their plants to one stem only. I think, however, that this is a waste of time. A well-managed plant will produce three blooms as good as one. A single-stemmed plant allows no margin whatever for injury. All side shoots ought to be removed as fast as they appear. It is a useless waste of energy to allow these surplus growths to remain until they are several inches long and then remove them. The present bright

and warm weather is having its influence upon well managed plants, which are making rapid and satisfactory progress. Continue to supply them with water at the roots as required. Newly-potted plants do not require the same quantity as those that have become well established. Any plants that exhibit a tendency to paleness in the foliage, like Miss D. Shea does for example, directly after potting ought to be kept rather dry at the roots for a time. Syringe the foliage twice daily. E. MOLYNEUX.

**Recent Chrysanthemums.**—Mr. Michael Barker, the editor of the "American Chrysanthemum Annual," has just edited another work with the above title. It forms Bulletin No. 91 of the horticultural division of the Cornell University, Ithaca, N.Y. There are several illustrations in black and white, and after giving a short review of the Chrysanthemum in America, notes on the cultivation of recent varieties grown at Cornell last year are supplied with dates when the buds were taken, and an opinion of their relative value. Most of the novelties are of American origin. Other chapters include methods of cultivation, insect friends and enemies, and the testing of varieties.

**Chrysanthemum Mile. Therese Rey.**—This splendid white Japanese variety raised by M. Ernest Calvat, of Grenoble, in 1892, and already well known to our exhibitors and growers, is now being distributed in Australia. An excellent full sized illustration of it appears in the *Australian Agriculturist* for the 1st of May last. Most of the leading show flowers in that colony are of European or American origin, but growers there are anticipating that their own seedlings will ere long occupy a much more prominent position. They are stated to be of a more robust constitution than the imported varieties.

**Chrysanthemums in Australia.**—Seedlings are now being raised in Australia. Last year one of my correspondents spoke very highly of one that had been raised in Victoria called *Pride of Madford*, an incurved Japanese, colour bluish purple, with a silvery reverse. I notice in the "American Chrysanthemum Annual" that Mr. H. J. Carter, of Sydney, refers to it as a beautiful Melbourne variety. Since then I have received a report of the Sydney Chrysanthemum show held in April last. Some colonial raised seedlings of great promise were staged, and the floral committee of the Horticultural Society there awarded the majority of them first class certificates. The principal raisers appear to be in New South Wales—Mr. G. H. Kerslake, Mr. J. H. Horton, Mr. S. B. Levick, and Mr. J. Upton. The names of the flowers were G. H. Kerslake, a white Japanese, with long drooping petals; Oceana, an incurved Japanese, with broad petals, colour clear yellow; *Pride of Ellwood*, a reflexed Japanese, with long petals, colour amber-yellow; Mrs. J. H. Horton, a Japanese incurved, old gold suffused with salmon, reverse buff; Minembah, a Japanese, colour deep yellow, lined reddish brown, reverse pale yellow; Samuel Upton, Japanese incurved, of deep rosy amaranth, with reverse silvery; Mr. James Toohey, a Japanese incurved, colour pale lilac, reverse silvery; and Lady Gormanston, a seedling raised in Tasmania, but exhibited at Sydney, colour white, slightly tinged lilac.—C. H. P.

## SLATE AND OTHER ROOFS.

PREVIOUS to the development of railways the roofs of farmhouses, cottages, barns and sheds in southern and midland England were made of thatch and tiles—substances which with age assume hues of indescribable richness and delicacy and of infinite variety, thereby enhancing the charm of rural scenery. No one now dreams of employing any material except Welsh slate; unless, indeed, for outbuildings and the like, he descends to the greater obscenity of galvanised iron.

The prettily situated town of Luton is, for the most part, of recent growth; the house walls are of red brick, and here in Bedfordshire, forty years ago, it never would have occurred to any builder to make his roofs otherwise than of tiles or thatch, steeply pitched. Now there is not a brown or russet roof to be seen, the angle of the gables has been greatly enlarged, and the effect of an expanse of cold, yet shadowless slate, with closely clipped eaves, is utterly out of harmony with the surroundings. What has taken place at Luton is just what has happened to hundreds of other English towns, and, worse still, English villages.

The slate of Cumberland differs from that of Wales in being of coarser grain and less finely laminated. But it is of an exquisite greenish-grey, with silvery reflections and a glaucous bloom. It makes a beautiful roof, as many country houses in the north of England and south of Scotland testify, especially those built towards the close of last century. Besides this admirable material, in some parts of Cumberland and Westmoreland thin plates of limestone were of old the common roofing material. The porous texture of this stone renders it, under a moist atmosphere, favourable to the growth of Lichen, resulting in a many-tinted tapestry which is altogether delightful. Even here Welsh slate has begun to displace the native product. All round for miles, dotted on the grassy slopes, may be seen the grim, grey garths and hay barns, with stone roofs deeply stained with olive and russet, and splashed with golden Lichen. But the harmony is shattered by spick-and-span railway buildings roofed with Welsh slates; and even in the villages it is plain that the old fashion is falling out of favour, for all the new dwellings and the meeting-houses are roofed with the same material.

The close, crystalline texture of these slates enables them to resist all kindly vegetable pigment. It is true that sometimes near the sea a salt crust is deposited giving foothold to an orange Lichen which creeps over the surface with charming effect; but generally the tone remains unchanged, and rarely is a roof now put on with liberal eaves.

Matters are rather worse in Scotland. Nithsdale and Annandale once boasted a kind of roof peculiar to themselves. Thin rectangular flags of red sandstone, measuring 2 feet on the square, were prepared in the quarries of Lecharbriggs and Corncockle, and laid on diamond-fashion, formed an effective finish even to the humblest cot. But these are used no more, the Welsh slates everywhere being now seen. Few people are aware how much tile roofs were in use in Scotland from early times, and how greatly the scenery has suffered from their disuse. Those square border keeps which are such familiar objects in the Lowland landscape once had a very different appearance. There is preserved in the British Museum (Cottonian collection, "Titus," e. xiii., folio 76 87) a report on the military strength of the Western Marches by an English officer in 1563-66. This is illustrated by water-colour drawings of the chief strongholds and some of the towns in Dumfriesshire and Galloway. All the castles except Annan, and all the houses in the towns, are shown with steep red roofs—that is, roofs of tile. The churches have grey roofs of stone, and the tower of Annan has a blue roof, apparently meant for lead.

It may seem a small matter to complain of that, in a few years, English villages and Highland shielings will soon be uniformly sheeted with changeless mauve slate, and the complaint, as has been admitted, is a futile moan.—*Illustrated Gardener*.

**Notes from Chester.**—The Paeonies are in full splendour, rich reds, pale pinks, whites and creamy kinds as delightful in scent as they are varied in colour. Irises, too, are splendid, as beautiful as Orchids, with graceful outline wedded to simplicity of form and colour schemes all their own. Each of these families, however, is so large, that it would be a difficult matter to send specimens that would show fairly what they are like grouped in masses

as we see them here. From the herbaceous quarters we send you two *Inulas* which are grand just now, *I. glandulosa* with its tangled fringed fringe of golden coloured ray florets about its cone of gold, and *I. Oculus Christi*, not quite so large, its crown flatter and its fringed gold lace of deeper orange. *Campanula persicifolia alba* is splendid just now. The gay rosy *Catchfly* (*Lychnis viscaria splendens* fl.-pl.) makes a red ridge of well-defined colour and lasts long. *Polemonium Richardsoni* album and *Aster alpinus rubra* are both beautiful and valuable acquisitions. In addition we send some flowering shrubs. The two *Brooms* are lovely, *Cytisus scoparius pallidus* is literally crowded with its yellow blossoms, and *Cytisus trifoliata* is rich and compact, whilst the healthy green of its foliage tells with marked effect. *Potentilla fruticosa* is full of its delicate cup-like blossoms, and the *Allspice* (*Calycanthus floridus*), with its rich brown-purple flowers, is a conspicuous occupant of the shrubbery border. We also send a few blooms of *Romneya Coulteri*, the Californian Poppy, for the sake of pointing out that with us the *Romneya* has stood the severity of the winter out in the open without protection.—DICKSONS, Chester.

## NOTES OF THE WEEK.

**Dendrobium moschatum.**—I enclose you a raceme of *Dendrobium moschatum* to see what you think about it.—J. F. WILKINSON.

\*\* A fine raceme of this handsome species.—Ed.

**Strawberries from Burghley.**—Mr. Gilbert sends us some very fine specimens of Strawberry Searlet Queen, of which the flavour is excellent; also Royal Sovereign, the fruits immense, rather watery, and altogether too big for a pretty mouth. We do not gain much by bringing out such monstrous fruits.

**The Bermuda Buttercup** (*Oxalis cernua*).—I enclose a few flowers of the Bermuda Buttercup, which you may like to see. This plant has had some hundred blossoms on it and was very brilliant, but it closes except in bright sunshine. It has a sweet smell.—SCOTUS.

\*\* Large and pretty flowers of a clear yellow colour.—Ed.

**Polygonum capitatum.**—Most *Polygonums* are such robust growers that they can only be admitted to the roughest parts of a rock garden, but this variety is of very neat prostrate habit. The flowers, which are most freely produced, appear in globular heads of a pale pink colour about half an inch in diameter. The oval leaves are alternate on very short stems, they are green in colour, but deep red at the margin in apex, and covered with minute red hairs.—F. W. M.

**Chrysanthemum Zawadskyi.**—For bold effect in the rock garden few plants are more adapted than this handsome species, especially if kept on a ledge by itself. A small specimen planted less than two years ago at Exeter in Messrs. Veitch's rock garden now covers a space of nearly a square yard, the whole plant being one mass of large delicate pink flowers not more than 9 inches or 10 inches from the ground.—F. W. M.

**Anthericum liliastrium major.**—All the *Anthericums* are beautiful and useful, but the one under notice, however, is, I think, the best of the family. It is practically a miniature *Lilium Harrisii*. I saw a bed of it the other day in Messrs. Jeffries and Son's nursery in full bloom, which was lovely. A finer border plant would be difficult to find. Although *A. liliastrium* is a fine old garden plant, the major var. is in every way much finer, and one of the best flowers for cutting I know.—THOS. ARNOLD.

**Mertensia virginica.**—I noticed on page 421 of THE GARDEN for June 15, and also in "Notes of the Week" in THE GARDEN of June 8, allusion is made to *Mertensia virginica* being in fine flower. Surely this must mean *M. sibirica*, as I

believe I am correct in stating *M. virginica* to be a March and early April blooming plant, making a grand show where not out by early frosts, and not continuous in flowering like *M. sibirica*. I shall be glad to know if it is not a mistake mentioning *M. virginica* as being in flower at the present season—that is in June.—M. P.

**Hemerocallis flava.**—This fine hardy plant is doing exceedingly well here this year; I have never before seen it so fine. One specimen has over fifty flower-stems, most of which are bearing eight flowers or buds and are over 3 feet high. Altogether it is the most perfect specimen of its kind that I have ever seen, and having so many flower-stems the number of flowers open at one time is much larger than usual and makes a display that would be impossible with a smaller plant. I counted to-day a hundred flowers open on the one specimen.—J. C. TALLACK.

**Carpenteria californica.**—The large specimen of this flowering shrub shown by Mr. J. T. Bennett-Poë at the Drill Hall on Tuesday was a fine example of cultural skill, as it was luxuriant in vigour and most profusely bloomed, being literally covered with fine clusters of flowers. There are a number of choice and beautiful flowering shrubs not quite hardy enough to withstand our winters well worthy of such treatment as this *Carpenteria* has received, but the general rule, unfortunately, is because they cannot quite be trusted in the open air they are not grown at all. This plant was one of the features of the meeting, and was much admired.

**Hedysarum multijugum.**—Some time ago this beautiful Chinese shrub was mentioned in THE GARDEN as having stood the test of the last severe winter. It is now a mass of flower on a rocky bank at Exeter, and its long shoots covered with crimson-purple flowers look most graceful and effective. It requires a well-drained soil and full exposure to the sun.—F. W. MEYER, Exeter.

\*\* This shrub was also flowering freely at Kew recently, where we saw a little bed filled with it, and a graceful light group it made, the shoots being slender, the leaves long and narrow, with tiny leaflets, and the rosy purple flowers disposed thinly in long racemes. It would be most effective planted in association with some other choice shrub that flowered at the same time, some of the pretty *Brooms*, for example.—Ed.

**Saxifraga flagellaris.**—This is a most distinct and handsome Reekfool, introduced from Colorado, where it grows at a very high altitude, but, according to good authority, it also occurs on the Caucasus. Messrs. Veitch (Exeter) received some plants of it last autumn and it is now in full bloom. The flower-stems are hairy and viscid, each stem bearing (3 inches or 4 inches above the ground) three bright yellow flowers comparatively large in size. The foliage is more like that of a *Sempervivum* than a *Saxifraga*. The thick, fleshy leaves are green and smooth, with hairs on the margin only, and form an incurved rosette not much more than 1 inch in diameter. Most curious is the way the plant reproduces itself by thread-like stolons, each terminating in a tiny rosette.—F. W. M.

**A few good Spanish Irises.**—There are many varieties in catalogues that it is perplexing to discover the best. When in the Long Ditton Nursery recently we noticed large beds of the following kinds, all of great richness and beauty, showing to advantage in a mass: Princess Ida has whitish standards and yellow falls, a pleasing contrast; Oberwinaar is of a lovely citron-yellow shade, peculiarly clear and beautiful; Louise, pale blue; Golden King, intense yellow, very handsome; Don Quixote, shades of blue, a charming Iris; and Donna Maria, also shades of blue. We are pleased to know that Spanish Irises are grown well in many gardens and nurseries. They form a delightful and important class of hardy bulbs.

**Papaver pilosum.**—This little-grown Poppy is deserving of more favour than is generally accorded to it. At the present time a patch

6 feet long by 3 feet wide is in flower and will remain so for another month. The plants average a little over 2 feet in height, and being thickly planted, spread in the morning, a canopy of orange-buff above the bed, the petals being, however, of such delicate fashioning, that a few hours' sunlight sees them fade, to be replaced by fresh flowers at the next dawn. The individual plants perfect from 100 to 150 blooms, are quite hardy, and want little or no attention, growing in the wild garden as freely as in the bed; but wherever grown, this Poppy should be planted in masses, as, on account of the fugitive character of its blooms, single specimens give but a poor idea of its effectiveness in colonies.—S. W. F.

**Abelia triflora.**—One is often asked for the name of a shrub for covering a wall that is out of the common lists of wall trees. This pretty North Indian shrub, now that it is beautiful in flower, appeals to one. Out of flower it is not remarkable, but when covered with clusters of pale pink flowers most people would think it a refined and beautiful shrub. The perfume, too, is sweet, and that in a wall shrub is to be considered when planted against a house near windows. Unfortunately, it is not a "stock" plant in nurseries, so there is always some difficulty in getting it. It is in full flower, and will be for another week or more, against the herbaceous ground wall (east side) at Kew. A coloured plate of it may be seen in the tenth volume of THE GARDEN.—W. G., Kew.

**Frost in the middle of June.**—For several nights we have experienced slight frosts, but the worst occurred on the morning of June 15. On high ground well above the river Wye we registered 2°, which must have been considerably exceeded in the lower parts of Ross, as all the Potatoes, Kidney Beans, and Vegetable Marrows were blackened and cut down to the soil. So far as I can learn, fruit suffered no damage.—ROSS.

— On Friday night, the 15th inst., there was a very sharp frost (7°) here in this locality, doing great damage to growing crops, especially Potatoes; even those that were earthed and 12 inches high are killed to the ground, while Searlet Runners and Kidney Beans are completely ruined. Trees and shrubs have suffered. The Spruce and Rhododendrons in new growth were a beautiful green, but now they are the same as they were after the winter, and all the young growth is killed. Laurels and Beech are similar. It is quite the exception to have frost here so late in the year; they often have it in the dales when we see no signs on the hills.—C. REEVES, *Two Dales, Matlock*.

**The great white Campanula.**—There are several beautiful white Bellflowers, but the most lovely is without question that which is burdened with the embrous name *Campanula persicifolia grandiflora alba*. I should have no hesitation in naming it as the finest white hardy border flower we have in gardens. It is far and away superior to what is simply called *C. persicifolia alba*. Its flowers are not only larger, have longer and more pointed corolla lobes, but while the former is a cold white, the best sort has a suspicion of purple, which gives a soft whiteness to the flowers. On light soils it is very hardy, and though never one of the most robust growers, it is certain to appear in due season and give weeks of abundant blossom. I do not know another flower that combines so much beauty of form in its flower and elegance in growth with such purity of petal. The fine masses of it that for some time past have made a border at Kew (by the Cambridge Cottage wall) a great attraction, to even the most indifferent of the visitors, show well what a grand border flower it is. The chief point in obtaining it is to observe the name *grandiflora alba* and see that you get the plant.—W. G., Kew.

**Haplocarpha Leichtlini.**—This South African perennial composite (lately introduced by the well-known M. Max Leichtlin, of Baden-Baden) is now blooming abundantly in Messrs. Veitch's nurseries at Exeter. The plant has a peculiar *Gazania*-like appearance and (with the

exception of the colour) somewhat resembles *Gerbera Jamesoni*, but is more sturdy. The leaves are cauline, arranged in a rosette lying almost flat on the ground, individually 6 inches to 8 inches long, deeply lobed, about 2½ inches wide, but very narrow at the base. The upper side of the leaves is deep green, but the underside is covered with a thick woolly coating to such an extent as to appear completely white. The composite yellow flowers are borne on stems 8 inches long, each flower-head measuring 2½ inches in diameter. The outer or ray florets are of a bright golden yellow, while the disc florets are of an orange colour. The involucre bracts are of a brownish tint and covered with pubescence. This woolly coating extends all the way down the stem, but does not entirely hide the brown ribs of the latter. The plants growing at Exeter are doing well in a sunny position in stony soil and are very striking in appearance. If it proves sufficiently hardy to stand the winter without protection, it will be a most desirable acquisition for the rock garden.—F. W. M.

**Herbaceous Pæonies at Long Ditton.**—A few days ago in the nurseries of Messrs. Barr and Son, Long Ditton, the herbaceous Pæonies were remarkably fine, though the fierce sunlight has spoiled the blooms to a great extent. One sees in such a collection as this how greatly the Pæony has been improved upon, the newer varieties having very large yet not coarse flowers, full, sweetly scented and delicately coloured. It is impossible to note all the good kinds in flower, but we selected the following as specially worth mention. Of the double varieties the finest were *Princess Clothilde*, white, with large flesh coloured guard petals, passing to white and scented like a Rose; *Eugene Verdier*, white and bush, a lovely kind; *Agnes Barr*, yellow centre when the bloom first opens, but passing to white, and set off by large rosy coloured guard petals; *Auguste Milleiz*, white and rose; *Solfaterre*, opening yellow, but passing to white; *Comtess of Clancarty*, white, very full; *Sir Henry Irving*, double rose, with deeper coloured buds, very free and rather late; *Mme. Furtado*, rose; *Mme. Defatry*, white; *Louis van Houtte*, a splendid crimson; *Prince Prosper*, deep crimson, with golden stamens; *Lord Salisbury*, very free, also of an intense crimson shade; *Leon*, white, with a few stripes of crimson-red on some of the petals; *Mme. Loise Mère*, late, very free, white, a dense compact flower; and the very late *Nimrod*, a deep rose flower. Of the singles, most charming were *Venus*, white and rose; *The Bude*, white; and *Queen of May*, rosy pink. These beautiful varieties last longer than many suppose, as testified by the plants in this nursery. We also noticed many promising seedlings, especially a single white, which we think better than those already in cultivation. The Pæony is a splendid June flower for massive growth, freedom and fulness of bloom, some varieties bearing flowers like a *Viscountess Folkestone Rose* for delicate shade and loose, graceful form.

**Notes from New Zealand.**—Mr. A. Dawson, of Hogarth House, Chiswick, sends us a letter lately received from New Zealand, from which the following notes will be of interest to many: "The last lot of Raspberries were almost a failure, but the first lot you sent have multiplied exceedingly, and will require vigorous treatment to prevent them becoming a fearful plague. They spread worse than Blackberries, and that is saying something. The whole space is a dense mass of suckers, and they almost killed the fruit-bearing canes. I shall cultivate them like hedges and wide enough apart to keep a horse cultivator at work. I am making a plantation of Blackberries in the same manner, as I have a splendid standard sort, growing canes nearly 6 ft. high, which I prune back to about 3 ft. 6 in. or 4 feet, and a spike loaded with berries is a sight. I should think that each cane averages nearly 2 quarts of berries. So it is a crop worth growing, the market price being about 2½d. to 3d. per quart. I have got a good lot of Tomato seed from this year's plants especially cured by drying up the apple and separating the seed, which I send by this mail. The Asparagus is

growing well. Some of it I have planted in its final position at once, whilst I have also made a nursery bed to see which does the best. I do not understand why the Cucumber seed should do so badly with you. I planted some of the same seed, and I have been getting lots of Cucumbers 24 inches long. I suppose they do not like going back to the colder climate. I took no special care with them, only just dibbling the seed in the ground here and there and they grow merrily. The fruit grows very rapidly and is extremely tender, so much so, that if you take up one by the end it snaps in two directly. The Japanese Plums are the thing to grow here. I have seen *Ogon* and *Satsuma* as large as Apples. Most of the varieties are sure and heavy croppers, so much so that heavy thinning is always necessary. You may see quite a crop on a two-year-old tree. The Botan ought to do well with you. My outdoor Vines are all doing splendidly, each Vine of one stem about 8 feet long trained about 1 foot above the ground bearing fifty bunches—of course, far too many, but we cut off the extra bunches when the berries are the size of Peas and turn them into jam, which could not be distinguished from Gooseberry jam in flavour.

## PUBLIC GARDENS.

**A present to Durham.**—Viscount Boyne has presented the inhabitants of Wellington, Durham, with 18 acres of land, sloping towards the river Wear, for the purposes of a public park.

**Metropolitan Gardens Association.**—At the monthly meeting of the Metropolitan Public Gardens Association, Lancaster Gate, the Earl of Meath presiding, fourteen new members were elected, and a communication was read from the City Parochial Foundation stating that the governors were willing to render assistance to the extent of £1000 to certain schemes of the association of which they might approve, for the provision of smaller open spaces. It was announced that the association had completed and opened St. Peter's Churchyard, Walworth, on the 23rd ult., and Woolwich Churchyard on the 31st ult. It was stated that the completion and formal opening of the riverside ground at Battersea would have to be deferred for some months, pending the formation of a new road; meanwhile the public were able to use the ground in its unfinished condition. It was hoped that the laying out of the disused burial-ground in Long Lane would be shortly begun. It was agreed to take steps to acquire a similar ground in Woolwich, and to grant applications for seats for Chiswick, East Ham, and Canning Town. The chairman mentioned that the Museums and Gymnasiums Amendment Bill had passed the second reading in the House of Lords, and that the London County Council had invited the association to the public opening of the Bethnal Green Poor's Land, a piece of ground which had been saved from the builders some years ago by the joint efforts of the association and a local committee.

**The weather in West Herts.**—There have been no particularly warm or cold days during the past week, but all the nights have been cold for the time of year, and on those preceding the 13th and 15th 2° and 4° of frost were respectively indicated by the thermometer exposed on the lawn. No damage was done by these frosts in my garden, but on Berkhamsted Common a good deal of the young Braeken has been killed. The temperature of the ground at 2 feet deep now stands at 62°, and at 1 foot deep at 65°. At the latter depth the reading is 4° above the June average and 5° warmer than at the same date last year. A little rain fell during the night of the 18th, but only sufficient to lay the dust. The drought still holds; in fact, since the middle of May, or for five weeks, there has been no rain worth mentioning. The total rainfall of the last

four months, which were all dry ones, falls short of the average by as much as 4 inches, or about double the amount usually deposited in any one of these months. No measurable quantity of rain water has come through the light soil percolation gauge for forty-six days, and none at all since the middle of May. During the past fortnight the air has been unusually dry, the average difference between the readings of the dry and wet bulb thermometers at three o'clock in the afternoon being 13°. During the same fortnight last year the mean difference was only 5°.—E. M., *Berkhamsted*.

**A horticultural impostor.**—There is a man going about the country who is pleading poverty, said to be brought about through ill health. He professes to be an expert propagator, having been in the employment of Messrs. Henderson, Pine-apple Nurseries, and having raised *Allamanda Hendersoni*, *Pimelea amabilis*, and many other good things. He came to me with letters of reference, &c. I helped him by giving him sufficient money to procure a bed and refreshments for the evening, also recommended him to a friend who found him employment; but of this he soon became tired and retired to the nearest public-house, where he soon spent his last sixpence. Going back to my friend with fair promises, he was once more put to work, but, alas, this soon proved too much for him, and he once again found his way to the public-house. This time he was very abusive to my friend. He then came back to me, and not knowing what had happened or that he had been employed, I further assisted him. He then borrowed my "Garden Annual," professing that he wanted to find the address of a relative or friend. I have not seen the man or my "Garden Annual" since. My friend tells me that while he was with him he received a P.O. for a considerable amount. He is about 5 feet in height, sixty-five years of age, and has sandy whiskers. Such an impostor should be punished.—THOMAS ARNOLD, *Cirencester House Gardens*.

## OBITUARY.

**Death of Mr. R. C. Kingston.**—Many will hear with regret of the death of the well-known gardener and estate manager of Brantingham Thorpe, who, after a short illness of only a few hours, died on Thursday, June 6, at the age of 77. He was a foreman at Chiswick for some years, and in the year 1841 took charge of the gardens at Brantingham Thorpe, where in a very few years he became well known as a most successful exhibitor.

**Flies and beetles** (*A. S. A., Marple Bridge*).—The two flies you sent are specimens of *Leptis scolopaea*, a very common insect. The beetle is *Telephorus fuscus*, commonly known as sailors, also a very common insect. Neither the fly nor the beetle will do any harm in gardens.—G. S.

**Royal Horticultural Society.**—The next meeting of the Royal Horticultural Society will be held in the Drill Hall, James Street, Westminster, on Tuesday, June 25, when special prizes will be offered for hardy herbaceous flowers. Professor Henslow will give a conversational lecture on some of the most interesting plants in the day's exhibition.

**Names of plants.**—E. S.—1, *Robinia Pseudacacia*; 2, *Anthericum liliastrum*; 3, *Clematis paniculata*.—*Campione*.—*Fuchsia fulgens*.—E. F. T.—1, *Lilium Martagon*; 2, *Spiraea filipendula*; 3, *Hemerocallis flava*; 4, *Centaurea montana*; 5, *Iris graninea latifolia*; 6, *Allium Moly*.—C. B. B.—1, *Saxifraga tritricata*; 2, *Helianthemum vulgare* var.; 3, *Dianthus plumarius*; 4, *Aster alpinus*.—G. G. C.—The shoot sent looks like that of *Viburnum Opulus*, the wild form of the garden Snowball Tree, and a pretty flowering and berry-bearing shrub that grows well in wet places.

No. 1232. SATURDAY, June 29, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHIDS.

## NOTES ON CATTLEYAS.

THERE is not a month in the year in which the flowers of this most important and beautiful genus may not be enjoyed, the labiata section alone keeping up a constant succession of their gorgeous blossoms from January to December. Besides these the guttatum and bicolor types make a pleasing change, and perhaps in some cases these are even more looked forward to than the former groups. The great majority of Cattleyas are among the easiest of Orchids to cultivate provided healthy and well-established plants are procured in the first place, but if they once get into a really bad condition there are few more difficult to bring round. This does not apply to newly-imported plants, no matter what their condition, as they are established with greater ease than some other genera, but wholly to ill-cultivated specimens in our Orchid houses. The pseudo-bulbs and leaves of the former are only shrivelled from want of heat and moisture, in the presence of which the latent buds at the bases will soon push strongly into growth, and in a few seasons the plants are as strong and healthy as ever. The latter, on the other hand, through years of ill-considered treatment have fallen into a thoroughly debilitated state, and from this they seldom recover. Although several of the species require more heat than the rest, this can usually be arranged by a little care in arrangement in one house; still where more heat is at command it is as well to remove thereto at least *C. Dowiana*, its variety *aurea* and *C. superba*, as these of all others delight in ample heat. The Cattleya house should be fairly lofty, well ventilated and light, the best aspect being a house running due north and south. The minimum winter temperature must be as near 55° as possible, rising to 60° by day with fire heat. In summer 70° is ample in the absence of sun, but when bright the temperature will of course run much higher. A close or stuffy atmosphere must always be guarded against by judicious ventilation, as nothing so tends to the propagation of insects, the growth under these conditions being also unsatisfactory. One of the most distinct species now flowering is

*C. ACLANDLE*, a very beautiful and somewhat variable kind, introduced in 1839 from Brazil. If proper care is taken to keep the plants moist, this Cattleya is most satisfactory on fairly large blocks, and these must be suspended to get the full benefit of light and air. In winter the utmost care is needed, as in the somewhat dry atmosphere prevailing at this time the blocks soon part with the moisture, and a watch must be kept or the small pseudo-bulbs shrivel and lose their energy. It grows about 6 inches high, and the pseudo-bulbs each bear two leaves. The flowers frequently occur in pairs, and are about 4 inches across in the best forms. The colour of the sepals and petals is usually of a brownish green, beautifully spotted and streaked with purple and yellow. The lip is magenta veined with purple, spreading in front, but narrowed at the base. If grown in pots or baskets only a very little compost must be allowed and the plants disturbed as little as possible.

*C. GIGAS* is a noble species bearing very large, richly-coloured flowers. The pseudo-bulbs are short in comparison with the leaf, and it flowers upon the current year's growth. All of these

species require careful autumn treatment to avoid exciting them into growth before the winter, as unless this is done no flowers will be produced. It thrives well in suspended baskets and may be grown in the ordinary peat and Sphagnum mixture, this not being used in too great bulk. It is a native of New Grenada and has several varieties, the best forms usually flowering somewhat later than the type.

*C. HARRISONIANA* is a Brazilian species of considerable beauty, and very free-flowering. It is very erratic in its season of blooming and sometimes produces two flowering growths in a year. It grows about 18 inches high and produces the racemes from the top of the stems. The typical flower is rosy pink in ground colour, with a yellow stain on the lip. It has several varieties, including *maculata*, *candida* and *violacea*, the names of each being descriptive of the colour. The usual treatment as to temperature and compost suits this species, but it is well in all cases where possible to keep the plants entirely at rest during the winter. If growths push late in the season the plants should be allowed a little extra warmth in order to get them finished up without delay. *C. Harrisoniana* is an old species, having been introduced as far back as 1836.

*C. MOSSLE* is so well known and appreciated that any description is quite superfluous. It is, moreover, extremely variable, hardly two plants being exactly alike in all particulars. This, too, is sometimes late in finishing its growth, and is better for a full temperature during late summer and early autumn. It may be grown in pots or baskets either suspended or on the stage, and will never fail to give a good account of itself at flowering time. It was introduced in 1836 from Guayra and named in honour of a Mrs. Moss, of Liverpool. Another beautiful species of the labiata section is

*C. WARNERI*, which is a native of Brazil, introduced in or about 1859. This has large and richly-marked flowers, bright rose in ground colour, with a remarkably fine lip. The culture of this plant is not quite so easy as that of some others, but if attended to and kept as near as possible to its natural season of growth and rest, it will usually be satisfactory. This species ought never to be repotted until after it has flowered, as the roots that are then emitted from the base of the pseudo-bulbs re-establish the plants at once.

## WATERING ORCHIDS.

THERE is no more important operation connected with Orchid growing than watering, and none oftener mismanaged. To entrust this to a careless or thoughtless assistant would mean the positive ruin of the healthiest collection, and even the most experienced practitioner needs all his wits about him if the work is to be done with despatch. In watering a mixed house of Orchids this is especially the case, even when all are in full growth, allowance being always necessary for the condition of the compost, the position and comparative vigour of the plants. I never feel absolutely at home watering any plants that may have been purchased in pots until I have myself repotted them, for although one can form a fairly correct idea as to condition by the appearance of the compost and roots and the growth of the Sphagnum, it is not always to be relied on. Many nurserymen are, unfortunately, in the habit of repotting all plants sent out, or at any rate surface-dressing them, for the sake of appearance, whether they require it or not, and inexperienced cultivators are occasionally misled by the look of the plants. They commence to water just as if they were well established in the pots, only to find after a time that it has not only been labour in vain, but positively harmful to the plants, the damaged ends of the roots having decayed through over-abundant moisture. An oft-repeated question is, How often should I water such a plant? indicating perhaps a *Dendrobium* or an *Odontoglossum*. There could not well be a more absurd one, or one more difficult to answer.

Even supposing two species are in full growth, one may require syringing overhead, to another it may be injurious. The former will not need watering nearly as often as the latter. One may be suspended from the roof in a sunny position, the other standing in a shady, moist corner of the house. Again, the size of the pots, the thickness and quality of the rooting medium, the nature of the roots, and the length of time they have been potted must be studied and many more by the operator with the watering-can as he passes along. This seems a formidable array, but it is really not so when a little experience has been gained, but above all things I would warn amateur cultivators not to get into a careless way of watering. The plants may not appear to suffer; in fact, many may perhaps seem to be doing well, but a time of reckoning will come, and this probably when it is too late to arrest the backward tendency of the plants. Orchids differ in this respect from any other plants. One may have a houseful dry for a week even at this time of year and possibly only a few would show any ill-effects. Leave a house of ordinary greenhouse or stove plants for the same time, and most of them would be hanging over the pots dead or dying. Yet the mischief is done to the Orchids none the less, and it will show in time. It is just the same with overwatering. At potting time the decayed roots will be found; the effects of this will be seen by the subsequent weakly growth, and all for the want of a little intelligent reasoning or forethought. It is not within the scope of this note to quote the varying kinds or to give precise directions of any sort, more good being done by mentioning a few generalities or axioms to be observed. The atmospheric conditions outside will be noticed by the cultivator before he commences damping or watering. If the day is likely to prove dull or wet, or if the house for any reason is not quite up to the proper temperature, he will use no more water than is absolutely necessary, and will take great care that none is allowed near tender young growths or to collect in the axils of the leaves. But, on the other hand, should the air be clear and the sun bright, he will take care that the moisture applied to the roots and the atmosphere is adequate for the demands to be made on it by the need of the plants, and to replenish that wasted by drying winds and the sun's action. On such mornings an early start with the moisture is quite as necessary as with the ventilation, and for somewhat similar reasons. Many of the terrestrial kinds will be found to require proportionately more water at the roots than the epiphytal species, as they do not possess in a like degree the power of drawing their supplies from the atmosphere. This is an interesting faculty in Orchids, by the way, and will, I think, have to be considered more by growers than is at present the case. Besides what may be termed comprehensive details in connection with watering, there will always be individual circumstances to alter special cases, and each grower has to a certain extent to shape a course for himself. He may read the remarks of others and follow instructions given, but until he begins to reason for himself and attain a habit of close observation no real progress will be made.

R.

## HOW TO POPULARISE ORCHID GROWING.\*

As in everything else, I take it the first thing is observation; use your eyes properly, and you will soon see whether a plant looks ill or well, and this in Orchids is especially the case. A few days will often show you if a new plant is happy in its strange home. On the other hand, Orchids generally are the most long-suffering plants, and will take years before they actually die from ill-usage, so that there is time for a beginner to learn, and to experiment in all kinds of treatment. We cannot, I think, hope

\* Paper read by Mr. E. H. Woodall, F.R.H.S., before the Royal Horticultural Society, October 9, 1894.

to popularise Orchid growing until a fair idea of their modest needs is more common and widespread than it has been hitherto. This is, I think, the first point to be insisted on. The next and still more important point is to show that it is not necessary to have all manner of Orchid houses before a man embarks in Orchid growing; but, on the contrary, that a single house and a cold frame are all that are absolutely necessary for anyone who wishes to add a grace to the ordinary run of greenhouse plants. I must confess that it would be a great boon to the struggling amateur if the great nurserymen and importers could see their way to telling us briefly, when announcing an importation of new Orchids, whether these plants have been torn from tree-tops or whether they come from the crannies in the rocks; whether they come from the breezy hill-tops or from the steaming valleys; and it would indeed be satisfactory to know if they came from a dry or a wet climate, though, broadly speaking, of course we expect Orchids to have come from a damp climate. We all should benefit greatly by such knowledge, because when a man finds his plants thriving he is much more likely to buy more and increase his collection than the man whose ignorance has made him half kill the plants under his care. An evil that would, I hope, be prevented, or at least greatly lessened, by proper information is the waste—I could almost say “wicked waste”—caused by tearing away these lovely creations from their native wilds, and perhaps entirely destroying them where they once grew so abundantly, only to kill them in a foreign land; whereas, with proper knowledge and cultivation, it will be possible to say they are only transplanted, and not in any sense destroyed, so as not to rob the world of any of its bright jewels. The next condition, then, of popularising Orchids is to show they can be grown both easily and successfully. We all know that nothing succeeds like success, and if anyone can show how amateurs with small means, and possibly cramped positions, may yet enjoy a goodly harvest of beauty all the year round from their Orchids, I think it will not be long before fresh admirers will be tempted to try their hands at Orchid growing. The cultivation of cool Orchids is so well understood by all the large growers now-a-days, that it is a common sight to many of us to see these plants luxuriating by the thousand in long houses where nothing else is grown. This, unfortunately, inclines us to think they can only be grown well in this way; and what I want to-day to impress upon you is, that an amateur who has perhaps only one greenhouse and a frame may succeed in growing these cool—or, as I would rather prefer to call them to-day, “equatorial”—Orchids as well as those who have fine ranges of houses and all appliances at hand. I have too often heard it stated by successful Orchid growers that it is impossible to grow Orchids in an ordinary greenhouse; that it will be too hot and dry in summer or too cold in winter, and so on. Now I do not wish to contradict this statement exactly, because it is very nearly true; but yet I think I can suggest a plan—a very simple plan—by which cool Orchids may be grown by those who may have only one ordinary greenhouse where everyday flowers thrive. It will, of course, entail some care and some little arrangement, but I think it can be done very successfully, and great enjoyment reaped after a certain time.

About eight years ago, seized with the desire of growing cool Orchids, I bought a few dozen imported pieces and duly potted them with peat and Sphagnum and placed them in a rather close and stuffy fernery facing north. After a

year's trial I was so much disappointed at their want of progress, and the absence of vigorous growth, or any sign of flower, that I felt something must be done or my plants would dwindle to nothing; so after much cogitation and reading of any book I could get hold of which told me of the countries where these plants came from, I excavated a space under a north wall to a depth of 18 inches, and bricked and cemented the bottom and sides, so that it became watertight. Over this I placed a three-light frame, facing also to the north, and then placed my poor invalid Orchids on inverted pots standing in the water covering the bottom. This was in the end of June, when the nights were just getting mild and genial in the north of England, where the garden is situated. Before I go further I think I should explain what made me try this, as I had heard, of course, of Orchids being placed in cold frames during the summer; and yet I never found anyone who seemed very successful in consequence of so doing. Those Orchids we call cool Orchids grow at high elevations on mountains under the Equator, where there is neither any summer nor any winter season such as we have in northern latitudes; consequently they neither have summer heat nor winter cold, and in the close, damp woods where many of them thrive the atmosphere is always moist. The light is constant all the year round, there are no short, dark days and no fierce, drying sunshine or winds to blast them; yet the nights there are always cool, and the intensity of the light such and so constant, that the shade is tempered to a degree we have little idea of. It seemed to me probable, then, that if I could manage to reproduce their natural condition of moisture, air, and light sufficiently perfectly in summer they might endure our dark winter days without much loss of strength. With this idea, then, I put my Orchids into this cold frame facing north, and with an inch or two of water covering the bottom. On every still, mild night the lights were entirely drawn off, so that the plants should get all the dew and cool night air and every drop of rain that fell. On windy, dry nights the frame was closed. During the day it was aired but slightly and shaded rather heavily to prevent the sun raising the temperature much; but whenever it rained the lights were always drawn off entirely. By this means the plants in a wet summer never required any watering beyond what they received as dew and rain; they were cool and moist both by day and night, and yet had abundance of air, unless a high and drying wind prevailed; and I watched the result of my little experiment with much interest. After the first shock had passed, caused by the change from the fernery to a cold frame with the lights off at night, I saw a steady improvement set in: the young growths took new life; the old pseudo-bulbs became plump; fresh roots appeared everywhere amid the green and rampant Sphagnum, which found itself once more as if on its native heath; and by the end of September, when I took my plants again indoors, they looked as much better for the tonic open-air treatment they had enjoyed as any young party of children ever did fresh from a trip from the seaside.

Pleased as I was at the unexpectedly great success of the frame treatment, I did not put them again in the fernery facing north for the winter, but boldly placed them in a cold plant house where Roses and Azaleas thrive, and the useful and ornamental Chrysanthemum blooms in autumn, as I was so satisfied that plenty of fresh air and light had much to do with their health. I gave them an eastern aspect close to the glass and with a saucer of water beneath

each inverted pot, so that there should be no lack of air-moisture, and no need to deprive other plants of their accustomed ventilation. Here they continued to thrive until really severe weather rather checked some of them, but with the first return of spring all went well, till I had to devise canvas screens and shading to keep off the March sun and March east winds. By this means I was able to keep them in good health till the joyful time came round for turning them out again into their summer quarters. This second summer they grew away at once with increased vigour, and by the time the first chill of autumn came in September I was able to show fine spikes of bloom pushing up from really fine, strong, healthy plants. I will not weary you with more details as to potting, &c., but merely say that from that day in 1885, when I first put out these Orchids, till the extraordinarily hot and dry year of 1893 I never had a check to my success. In that exceptionally hot and dry year of 1893, when no rain fell for weeks together, and nights were as hot and as dry as the days, these Orchids did not do nearly so well as usual. A few, indeed, really suffered, showing, I think, how inferior a watering-can is to the gracious rain and dew of heaven, which are life and strength to all alpine Orchids, and a sure means of recovery to plants that have exhausted themselves by flowering. Each year I have tried some fresh species of Orchid in this frame, and generally have found it succeed. I must not forget to say that the cold plant house treatment in winter is quite as satisfactory as I could desire till March suns are blazing on the eastern glass. A north aspect with reed blinds would no doubt then be preferable, but I wish to show it is not necessary to have special houses and special aspects for these equatorial Orchids.

When I first began growing Orchids in this way I only put out into the cold frame *Odontoglossum crispum*, *O. Pescatorei*, *O. gloriosum*, *O. hebraicum*, *O. triumphans*, *O. Rossi majus*, *O. maculatum* and such intermediate forms as I possessed. I now place in the frame such as *Epidendrum vitellinum*, *Odontoglossum grande*, *Ada aurantiaca*, *Trichosma suavis*, *Cochlioda Noetziiana*, all of which enjoy their summer outing enormously, and will winter in a cold house. *Oncidium*s I find the most intractable; they enjoy the plant-house winter quarters, but do not thrive with this cold frame and open air treatment. They need, I think, more sun and air by day and a warmer night temperature than we usually enjoy in Yorkshire. For them I have thrown out a window-case opening from the plant house, always open to it and well exposed to the eastern sun. Like the frame, the bottom of this stand is cemented so as to hold water and create a moist atmosphere, in spite of the abundant ventilation in the plant house. Here a few Orchids that did not like the cooler treatment have done well, specially *Oncidium Gardneri*, *O. Forbesi*, *O. varicosum*, *O. concolor*, *O. dasystyle*, *O. cheiroporum*, *Pleione lagenaria*, *P. Wallichii*, *P. Reichenbachiana*, which thrive well under plant house conditions in winter and flower capitably in autumn. There are several others that do well with me in the ordinary plant house—*Disa grandiflora*, for instance—but I prefer to plunge it out of doors, after flowering, in a shady spot, and not bring it back till I pull it to pieces and repot the young growths in October. *Cypripedium insigne montanum* and the hybrid *C. Leeaanum* thrive extremely well under the shade of the Azaleas, and need no change of quarters all the year round. *Cattleya citrina* thrives in this same house from March to November, but it

needs a warmer and moister house in winter when it is making its growth. It should, however, be replaced in a shady nook of the cold house in March when the flower-buds are first visible, or it will be weakened for another year. There is another Orchid I would mention as enjoying summer frame treatment, which needs warm or intermediate winter quarters—that is, *Miltonia vexillaria*. I have not mentioned it before, because it will not stand really cold winter weather in the plant house, but no Orchid more thoroughly enjoys frame treatment in summer. There is one Orchid I have found absolutely intractable. This is *Oncidium crispum*, and if anyone will tell me how to keep it in good health for more than two or three years I shall be most delighted to try his plan.

I have now made out, I think, a very sufficient list of Orchids that can be well grown by those who possess one greenhouse and a frame or two, and if I can persuade anyone living in fairly pure air to try my plan I feel sure it will succeed. For those in smoky districts, where the air and rain are laden with chemical products and sooty impurities, I can only say for their consolation that *Cypripedium* seem singularly able to stand smoke, and that if *Sphagnum* will stand the sooty rain, the Orchids too will do the same. It is a curious instance of the adaptability of Nature that we should find *Sphagnum* our most valuable adjunct in growing Orchids, when it is unknown in their native habitats, and yet it is to us an almost infallible proof that conditions are favourable for our cool Orchids when it is green and flourishing. Just as when one translates a book into a foreign tongue the idea must remain the same, while the words themselves are changed, so must our Orchids have the same conditions, while their surroundings may be utterly changed. I must not forget to add that if any Orchids show bloom while in the frame I take them out when ready to expand and place them in the shadiest part of the plant house, so that the petals shall not get spotted by damp or dashed by heavy rains. In many instances I find they last longest in a sitting-room where no gas is burned at night, and I do not find the plants injured seriously when grown in this hardy fashion. An Orchid I should specially like to recommend to amateurs as suitable for an ordinary cold plant house in winter is *Disa grandiflora*. This is an Orchid that is considered difficult to grow near London, and it is, no doubt, so sensitive to smoke or any impurity in the air that only those who live in the country should attempt it. For those, however, whose gardens are in pure air, and who have plenty of soft or rain water for their plants, it is a plant that everyone who is a gardener should grow. Pot it in Fern-root and clinkers, putting each tuber against either clinkers or freestone lumps; surface with *Sphagnum* Moss or not, as you please, it is sure to do well in a cool and damp house near the glass in the winter; in the spring place it in a more shady corner, with a saucer of water beneath the inverted pot it should stand upon, and keep it syringed, well watered and free from fly or any pest till it has flowered, which should be in July or early August. Then plunge it outside under the shade of a hedge, and leave it, after once watering, to the dew and the rain. In October take up the pots, pull the young growths asunder, and start afresh for another year's round. To those who have a vinery and a tolerably warm house in which to winter their Orchids and other plants, I know of no more beautiful, lasting and delightful Orchid to grow than *Vanda cœrulea*. This too, is an Orchid

that has the reputation of being difficult to grow well and keep in health. I think, therefore, that if I state briefly the conditions under which it grows when at home, gardeners will see why they have failed so frequently. I have already mentioned how *Odontoglossums* grow under the Equator, and have spoken of the close, damp woods where they are found. *Vanda cœrulea*, on the contrary, grows on exposed hill-tops, on Oak trees, not close to the Equator, but on the verge of the Northern Tropic, and, of course, at a very considerable height, as it grows on so hardy a tree as an Oak, that is closely allied to our northern trees. What does all this mean? Surely that, in the first place, it delights in the full sweep of the wind (an exact contrast to the *Odontoglossums*); and, secondly, that it must have a winter and a summer, and therefore a wet and a dry season as well. We are told by meteorologists that when the sun is vertical—that is, straight over our heads at midday—then is always the time for those heavy rains we hear of in the Tropics; so then it follows that the summer is very wet and the winter cool and dry on the northern edge of the Tropics. The Oaks on which *Vanda cœrulea* grows are deciduous, we are told—another indication for us, if we will take the hint. Briefly, then, *Vanda cœrulea* requires plenty of moisture and abundance of air in summer, with a good canopy of leaves to shade it and keep it cool. In winter it needs all the sunshine it can get, with a dry, cool rest, close to the glass, always with as much air as can be given. Following out this idea, I have had great success the last five years with this Orchid, and I have carried out its treatment in this way. In March, when the Muscat vinery is first shut up and the Vines syringed, I put my baskets of *Vanda cœrulea* on a side shelf near the water-tank and close to the lower ventilators. Here they are treated just like the Vines, and are syringed well every day. As the sun gets hotter the Vine leaves grow, and by degrees the *Vandas* get heavily shaded; while in summer, when the Vines have abundance of air both at top and bottom, they are in a perfect gale of wind in our exposed garden when west winds are blowing. Here they flower gloriously in August, September, and October; and I much regret that my fine old specimen, that had eight long spikes on it, with flowers 5 inches across and of the loveliest shade of tender blue, is now past its best, for I had hoped to have shown it to you as the result of five years' growth. In November, when the *Chrysanthemums* are in this house, I think it wise to put the *Vandas* into more warmth till the sun is gaining new power in the first days of February. I then hang them up near the ventilators in a little span-roofed house where we grow Carnations, Geraniums, Primulas, and such plants. They are kept very dry now, having been gradually allowed to rest through the dark days; and unless they shrivel I do not give them water at all, as I find the one essential is a perfect and somewhat prolonged rest in cool, dry air. To see the way these yellow sun-burned leaves turn green and fresh, and to see the vigorous young roots push when in spring these baskets, after being resurfaced and dressed with fresh Fern root and Moss, are placed anew in the genial atmosphere of the vinery, is a delight to a gardener who likes to see his plants happy; and though I should fear "spot," which comes from damp and want of air, I do not mind a little shrivelling or yellowing of leaves in early spring, knowing well how necessary this cool, dry rest is to their well-being and free-flowering later on. I need hardly say this is especially an Orchid that

needs a pure air and a clear sky in winter. I think I have now trespassed sufficiently on your patience, and can only hope I have made myself clear enough to tempt new beginners to try these Orchids. They will inevitably try their hand at others. My experience leads me, at any rate, to this conclusion.

#### NOTES FROM A NEW ZEALAND GARDEN.

To admit that one may have too many Daffodils is to admit a great deal, and I will not be brought to the admission except it appear that my stock has reached that point when increase in quantity must be made at the expense of quality. But I have my fears. This year I have been replanting by the thousand, and my experience meanwhile has not been entirely satisfactory. Every Daffodil grower knows the pleasure of handling a fair-sized, well-ripened, and well-shaped bulb, brown, firm, and silky like an Onion. For my own part my pleasure in the bulb is little less than my enjoyment of the flower. But little of that pleasure have I had this year, though I have planted so extensively. In the case of some varieties, though the bulbs are fairly large and healthy, they have, from overcrowding, become laterally compressed in a way no grower of Daffodils can approve, whilst the outer skin has not the silky brown gloss that the epidermis of a perfect bulb ought to have. *Empress* has, I think, under any conditions of growth an ugly bulb in contrast with the fine, large, smooth-skinned bulb of *Emperor*. I have more than once remarked the difficulty of distinguishing *Empress* from *Horsfieldi*, and I have pointed out in former notes that they are distinguishable by their relative seed-bearing qualities, *Empress* being almost or entirely sterile, and *Horsfieldi* fairly fertile. I notice also that they differ markedly in the shape of their bulbs, that of *Horsfieldi* being flatter and fatter of the two.

As to the multiplying of varieties, I am entirely convinced that the number is already too large; and each season I resolve to extend my list no further, but each season when the new catalogues come in my good resolutions go to the wall.

Writing of varieties, I am taken back across the years to a garden that knew no more than three varieties of *Narcissus*, and yet the Daffodil show of that old garden in the early days of April was not contemptible. It was a disgracefully utilitarian garden, and shockingly geometrical in design; a square of perhaps a couple of acres in extent. There was nothing about it that a modern aesthete would call picturesque, except perhaps its mortarless wall which so completely shut it in, that no glimpse of the inside was possible except through the pickets of the gate. The wall had originally been finished off with a thick coping of turf, and this in time had mellowed into loam, giving foothold to various kinds of waving Grasses, to patches of the common, but beautiful yellow-spored *Polypody* and rosettes of *Houseleek*.

I find it hard to believe that there exists now anywhere on earth a place so rich in wild flowers as the country-side in which that garden lay. It was one of those sub-alpine regions where you stand on the border-land, as it were, between the loveliness of the fertile lowlands and the stern loneliness of the granite hills. A walk of an hour or so would take you into a wilderness of heather, where in the peat-bogs you might find Bog Myrtle and Cotton Grass, Sundews and Butter-worts and *Sphagnum* Moss of all shades, green, yellow, pink and crimson. In the near neighbourhood of the garden the

most common weeds were lovely flowers—wild Thyme, Dandel, Brooklime, Bird's-foot Lotus, Harbell, Meadow-sweet, and so on. In the woods that lay around and by the mountain stream a stone-throw from the gate you might walk ankle-deep in Woodruff, Wood Anemone, and Marsh Marigold, knee-deep in Wood Hyacinths, thigh-deep in Lady Fern, and over the head in Foxglove, Bracken, and wild Raspberry. A few minutes would take you to the shady home of the *Trientalis europea*, Lily of the Valley, Oak Fern and Beech Fern, *Cystopteris fragilis* and *Asplenium nigrum*, *A. viride* and *A. Trichomanes*. Take a short walk in one direction and you might gather sheaves of Bog Iris; the same distance in another would bring you to the habitat of the fringed Bog Bean, rare of blossom. In autumn if you looked toward the hills they were purple with Heather, if toward the woods they were scarlet with the Mountain Ash (locally, "rodding"). As for Gorse and Broom, Dog Roses and Sweet Brier, Ivy, Bird Cherry and wild Cherry, they were abundant and glorious.

And yet in this richly-endowed district Nature had made strange omissions. Primroses there were in plenty, enough to make the air smell faint. But the Cowslip, which decks the English meadows with delight, was wanting. No child in that locality ever tasted Cowslip wine or threw a Cowslip ball. Nor were there sweet Violets beneath the hedges, though there were myriads of the scentless lilac kind, which we called the "Cuckoo Flower," because bird and blossom came at the same time; nor Meadow Saffron, nor Snowdrops, though there was a wood not ten miles away where they were as Grass; nor Hart's-tongue Fern, except in one hidden spot where those in the secret could get it by risking their necks, nor wild Narcissus of any kind.

Our forest trees may not have been so remarkable as our wild flowers; and yet, on second thoughts, I think they were. The finest autumn display of fireworks was made by a slope of Beeches that burned themselves away through a scale of brilliant colour into the light leather-brown of their winter leaves; and the same slope was just as beautiful in spring, as may be conceived, for what is more exquisitely delicate than the young foliage of the Beech? unless it be the young foliage of the Oak, a green with a yellow in it, seen in nothing else that I remember, except the Oak Fern, whence I take it this last has its name. Then there was the "Big Beech" covering who knows what area and giving shelter in its time to countless generations of children who played under its branches and fattened on its mast. The Beech accumulates its hardwood but slowly, and this particular Behemoth must have been centuries old. As for our Oaks, there are no doubt older, larger, and mossier Oaks elsewhere, but ours were old and large enough for me. Then there were hoary Spruces, the abode and breeding place of squirrels, miles of Larch, with its green and crimson tassels, sweetest of all the conifers, and each Larch seemed to have its chaffinch; silver Birches by every stream, Hollies too heavily berried for the birds to make an impression, cathedrals of Scotch Firs, coverts of Hazel, Ivy, the small-leaved wild kind everywhere; tangles of Honeysuckle and occasional colonies of Sloe or White Thorn. Further, these woods provided that without which no wood is perfect—solitude. You might wander through them a summer's day and meet none of your own species, nothing but harmless *ferre nature*, a pair of cushat doves or so, an occasional roe or squirrel, a pair of wood wrens or some small deer.

In this country lay the first Daffodil garden I knew—the appurtenance to an old, stone, Ivy-covered farmhouse, roofed atop with lichened slates, under which stray swarms of bees found harbourage; a utilitarian garden where flower, fruit, and vegetable grew in beauty side by side. A geometrical garden also, not that there were elaborate mathematical devices filled with the primary colours; curves there were none, the people who walked in that garden always taking the shortest distance between two points. Even the gardener who was put there to dress it and to keep it did his work in a toying, amateurish way, as if he were the garden's leisurely owner and no hired servant. The garden plan was simplicity itself—a broad grass walk forming a square, whose sides were parallel with the wall, and two broader grass walks dividing the first square into four shorter; along the sides of the walks, flowers, Gooseberry bushes and standard fruit trees; inside these, vegetables. The Gooseberries, as I remember them, were the sweetest in the world, the Apples the sourest. As for Pears and Plums they were a mockery, except for blossom, and that was splendid. The Apples (many of them) were little better than Crabs, but in blossom-time they were as fine as the best golden Pippins—finer indeed, for the blossom of the golden Pippin, I understand, is a trifle pale, whereas those sour, old Moss-covered Apple trees were hidden every spring in blossom, exquisitely flushed with pink, and some varieties were sweet and mellow even in the fruits: the small yellow, cracked Oslin, for instance, and the oval, brown-cheeked Jenny Sinclair. The Cherries were famous—blossom and fruit, more particularly one large wild Cherry tree, locally called by the French name *guigne*, which in spring, when it was a sheet of blossom, was the haunt of the cuckoo; and in autumn, when its branches were red with fruit, haunted by blackbirds and by other bipeds of a lighter colour. The Walnut trees on each side of the gate bore beautiful large Nuts with nothing in them, but Bacon must have had their leaves in his mind when he said that "certainly virtue is like precious odours—most fragrant when they are incensed or crushed."

As for flowers, they were not very numerous, or very various, or particularly choice. They were of the robust kind that, once planted, can hold their own; and yet they were sweet enough. There were bunches of Auriculas, black, snuff-brown, and yellow, which were seldom, if ever, transplanted; more particularly there were frequent bunches of an early Auricula that came with the Primrose—pale lilac, sweet-smelling, smooth-leaved and dustless. I believe it must have been the original alpine species, and I desire it now more than the finest green or grey-edged. Cabbage Roses were plentiful, feeble as to stem and foliage, but large and plethoric as to their flowers. "Cabbage" Roses, indeed! There were also crimson Damask Roses, long and filbert-shaped in the bud, and semi-double in the exposed state; also streaked York and Lancaster; also a white full-petalled summer Rose, which grew almost to a tree, sweetest of Roses for fragrance—*Rosa alba*, I suppose. There were purple Delphiniums and blue-veined Aconites—"Monks-hood," as we called it, or sometimes "Priests' Poison." There were Balm of Gilead, Rose of Sharon, Lily of the Valley, and no doubt other things known to Solomon; Hepatica and the blue Navelwort; Spiræas, Gardeners' Garters, the purple Flower-de-Luce, and Southernwood; on the summer house, Ivy, Traveller's Joy, yellow Corchorus, the larger Bindweed, and flowering Currant, the double red (which, strange to say, bore berries) and the single white. The

Lilac trees seemed to grow out of the stone wall, but their trusses of flower showed that they did not want for a good root-run.

Seeing that I began with Daffodils, all this may seem, as the French would say, "*apropos* of boots," but, in the manner of a *rondeau*, I return to my initial theme. Every year the garden had its "spring cleaning," so that by the 1st of April everything was spic and span—all dead matter removed, Raspberry canes and Gooseberry bushes severely trimmed, and the soil delved and raked. At this particular juncture the Daffodils availed themselves to come out in bunches innumerable, regularly marshalled like an army, and therefore somewhat formal in arrangement, but all the better suited to the style of the garden, which affected straight lines. With all my varieties of Daffodil and various styles of planting, I am afraid I have never produced any more telling effect than was seen every spring in that homely garden. Perhaps it is that bygone joys loom large through the mist of memory. Too well

I know, where'r I go,

That there hath passed away a glory from the earth.

But still I know also that the fairness of that garden was not altogether in the youth of the eyes that saw it. Yet it possessed only three varieties of Narcissus—a medium-sized Non-such Daffodil, *Narcissus odoratus*, and a *Narcissus poeticus*, which came a few days later than the Daffodil—ornatus, I should think, from its earliness. Nor was there any transplanting or thinning for twenty years at least, except perhaps when bulbs were given away. In my garden no Narcissus known to me would remain satisfied with this treatment. The bulbs would crowd and jostle each other, and ultimately the blooms would deteriorate. But that old garden had a light pebbly soil resting on a gravelly bottom; whereas my garden has a somewhat heavy loam resting on hard clay, and this may make the difference. However that may be, the multiplication of varieties becoming a matter for serious consideration.

A. W.

**Rosa indica.**—Perhaps one of the choicest of the wild Roses grown in gardens is this species, and it is one that many would cherish if only for the fact that it is one of the parents of the loveliest race of Roses, the Teas. But it appeals to us through its beauty, and a little bed of it at Kew is gay with many flowers, which are of a bright self-erimson colour and borne in clusters. It is one of the few species that bloom continuously, and although not so robust as most of its kindred, merits a favourable position and amply repays any extra care bestowed upon it.

**Epigæa repens.**—Being a great admirer of our Mayflower (*Epigæa repens*), I was interested in a recent GARDEN note which alluded to the lack of interest shown in its garden cultivation, speaking of it as "really too sweet a subject to be neglected." While I fully agree with this sentiment, experience has taught me that this charming and modest little wildling is one of the most difficult of all forest plants to grow successfully in the garden. Indeed, I have yet to see a single instance in which its obstinate wild wood nature was sufficiently subdued to make it succeed at all away from its habitat even under the greatest care in providing the most suitable conditions. Your writer speaks of the plant thriving best on an eastern aspect, which surprises me, because when I find it in this region it is always on a western slope or exposure, and usually on high ground where moisture can rarely accumulate. There is evidently very much for us to learn yet in regard to the requirements of this lovely little plant. But possibly if we knew it all we might not admire and appreciate it half as well.—H. HENDRICKS, Kingston, N. Y.

OFFINGTON.

THIS picturesque house and most interesting garden are only a short distance from Worthing. The visitor receives a pleasing impression the moment he sees the entrance lodge, which, embowered in creepers, is characteristically English; whilst native trees—notably the Scotch Fir on either side of the pleasant drive that leads to the house—are expressive of the most beautiful surroundings of an English home, compared with which the exotic conifers that so many plants are a poor substitute. In the garden itself Major Gaisford has gathered together, and grouped and arranged in an artistic manner, a perfect host of rare and beautiful trees, shrubs and plants which, favoured by a genial climate, give to the garden a distinctive aspect of its own. There is here an entire absence of that conventional, formal gardening which cuts up the pleasant turf, lays down hard, geometric patterns where we should see the free and graceful forms of choice shrubs and noble flowers massed

seeing it in flower some years ago. *Cesalpinia japonica* has survived in an exposed position, although moved last December. *Iris Lorteti* and *Eremurus robustus* are flowering well this year, and a plant of *Ostrowskia magnifica* has eight flowers on one spike, and they are all pure white.

*Abutilon vitifolium* does well here, and also the purple var. It stands all weathers and the flowers last for nearly two months. *Photinia serrulata*, twenty years old, bloomed strongly last year. We have never before seen it in flower in England in the open. *Pourthia villosa* (*Photinia*) is a beautiful shrub that does not appear in catalogues. It makes a mass of bloom in April 4 feet high. The leaves turn bright red in autumn. Veitch's hybrid *Phallageria* flowered here in the open border in 1893. The flowers are poor in colour and inferior to those of both of its parents, *Philesia* and *Lapageria*. The Burmese *Rosa gigantea* has run up to 15 feet, but has not flowered as yet. *Eupatorium Wit-*

at their first flowering produced salmon-coloured blossoms, but which subsequently bore flowers possessing the natural brilliant hue. The finest specimens of *Vallota* that have ever come under my notice have been grown in the windows of cottages and farmhouses, which situation and form of culture would seem admirably adapted to the requirements of the plants, inducing vigorous growth and free-flowering that must be seen to be credited.—S. W. F.

FLOWER GARDEN.

LILIUM ELEGANS.

THIS Lily, recently illustrated in THE GARDEN, is particularly remarkable for the great difference that exists between the several varieties in colour, height of the plant, and season of blooming. One variety is among the earliest of all Lilies to bloom in the open ground, for its blossoms follow closely on those of the greenish yellow *L. pyrenaicum*, which has been for some years the first member of the genus to flower. The variety referred to is a strong growing form that will reach a height of 18 inches to 2 feet, with large orange coloured flowers, irregularly shaded with red, and thickly dotted with brown. It is especially noticeable when growing, by reason of the young leaves and flower-buds being clothed with a whitish down, which to a great extent disappears before the blossoms expand. This Lily is very liberally treated in the matter of names, for it is known as *marmoratum aureum*, *robustum*, and *guttatum*. It is certainly a very distinct and striking form, valuable, too, from its earliness. Before the blossoms of this are faded away several other members of the *elegans* group are expanded, the first this year being *Prince of Orange*, one of the dwarfest of all Lilies, with pleasing yellow blossoms.

Quite a month later than the forms above mentioned is the variety *venustum* or *armeniacum*, whose flowers are of a pure unspotted apricot tint, very like those of the Japanese *L. Batemannii*. Widely as the varieties differ from each other in their season of blooming, they vary even more in the colour of their blossoms, ranging as they do from the pale buff-yellow of *alutaceum* and the somewhat richer tinted *Prince of Orange* to the deep blackish crimson of *hamatochromum*, *erucantum*, or *Horsmanni*, for it is known under all three of these names. Of flowers intermediate in colour between these two extremes we have *Alice Wilson*, rich yellow with a reddish shade, illustrated in THE GARDEN, November 8, 1890. Though it has been grown for some years this variety is still scarce and comparatively dear. On the same coloured plate with *Alice Wilson* was the form *Van Houttei*, one of the best of the bright crimson flowers. A very distinct variety in all stages of growth is *brevifolium*, with short, very dark green leaves and flowers of a kind of reddish salmon tint. This is one of the tallest varieties that we have, for it will reach a height of a couple of feet, while the little buff-coloured *alutaceum* is only about 6 inches high. From this it will be seen that the difference in height between the several varieties is also very marked. Besides all this, *L. elegans* is remarkable from the fact that

Offington House, Worthing. Engraved for THE GARDEN from a photograph sent by Miss Gaisford.

and blended. The large illustration shows the house nearly hidden by climbing plants and a grand old Ivy-embowered Walnut standing on a fine expanse of lawn. Beside the walk are large beds where the best hardy flowers have an opportunity to prove how much beauty they can impart to the garden where the plan of arrangement is large and simple in design. The smaller view shows the house from the flower garden, and the luxuriance of growth so early as Iris time is a remarkable contrast to the nakedness of most flower gardens at this period, when they are waiting to receive their summer occupants. Of the many plant treasures that are cherished here we need not now speak, as a good account of them may be found in THE GARDEN of July 13, 1889. Major Gaisford (writing to us recently) says now that the evidence of injury from the past winter is practically complete, he is surprised to find how few of the tender things are quite dead. Although many risky plants are grown, the actual losses do not number more than about 2 per cent. out of a total of nearly 700. The greatest loss is a *Fremontia californica*, which was on a west wall, where we remember

*mannianum* has lived in the open border for some five years, and the photo (of which an engraving appeared in THE GARDEN last week) shows it in bloom about Christmas Day last year. It is a South American shrub and was turned out of the greenhouse, being too large. *Cassia corymbosa* was in full bloom on a south wall till frost came, and *Physianthus albens* after two winters' frost has borne seed.

**Vallota purpurea.**—Most bulbs imported from the Cape flower during their first season in the spring, this being their time of blossoming in their native habitat. After a season or two, however, they flower at the same time as English-grown bulbs. I have a very beautiful variety of *Amaryllis belladonna*, which I brought back from the Cape, that flowered first during the month of March and on the second occasion in June, since when it has invariably bloomed in September. All the plants of *Vallota purpurea* that I have seen growing wild, and I have seen some thousands, carried blossoms of a vivid red, and I believe that the pale tinted blooms referred to on p. 414 as occurring occasionally in the case of imported bulbs are merely consequent on debility. I have had bulbs which

one of the varieties has double blossoms, which are not at all numerous in this genus. The varietal names of staminosum and flore-pleno have been applied to this double-flowered form. The petals of this are deep red, arranged in a cup-like manner, the interior of which is filled with flattened staminoïd segments, which give the flower a very singular appearance. Another double-flowered Lily (*Lilium tigrinum flore-pleno*) is in the duplex character of its blossoms totally distinct from the preceding. The flowers of this double variety of the Tiger Lily are composed of an extra number of petals, arranged in a regular manner so as to form a symmetrical shaped bloom. Of other Lilies, double blossoms are occasionally borne by the Japanese *L. auratum*, but this variety after the first season generally reverts to the normal form. A double variety of the Martagon Lily was at one time in cultivation, but I have not now seen it for some years. That form of the Madonna Lily (*candidum*) met with sometimes as flore-pleno and at others as monstrosum is a poor garden plant and at best only a curiosity. In this the petals are to a great extent suppressed, the entire head of bloom consisting of small bracts and petaloïd segments. When speaking of *L. elegans* I should have mentioned that it is frequently met with under the specific name of *Thunbergianum*.

T.

## NOTES FROM OAKWOOD.

RHEUM MOORCOFTIANUM is a distinct and rather attractive species of this family. It is dwarf, the flowers being arranged in a dense spike. Those who admire hardy fine-leaved plants should make note of this. *Pinguicula grandiflora* and *vulgaris* are quite at home in a rather damp place. Although of such small proportions, the lovely Lobelia-like blue of the flowers renders them quite ornamental. They have a very pretty appearance growing in this natural way. *Andromeda fastigiata* is a success growing in company with its near relative, *A. tetragona*. These little *Andromedas* are remarkably quaint-looking and worthy of a place where the necessary conditions can be secured them. *Lithospermum Gastoni* is doing well, as is also *Omphalodes Lucilia*, the bright Forget-me-not hue of which is very taking. It is growing on a mound where the drainage is very free. If this were as easy of culture as many of our spring flowers are, how valuable it would be. One can easily imagine the effect of a mass of it in full bloom. *Coronilla iberica* is a showy little thing, carpeting the ground with deep green foliage, which is thickly studded with bright yellow blossoms. It produces a nice effect in a somewhat elevated position. *Choisya ternata* was laden with its fragrant blooms. It is a charming thing for the open air, perfectly hardy, much more so apparently than many things reputed more so. Hundreds of blooms of *Aponogeton distachyon* were open in a shallow pond. The Cape Pondweed thrives like a weed at Wisley; in company with it are *Caltha palustris fl.-pl.*, the large, double, bright yellow flowers embellishing the water margin; and I was pleased to see our native Bog Bean (*Menyanthes*) occupying an honourable place. Seen in the form of a good-sized colony it is decidedly ornamental, quite as worthy of a place in gardens as many exotics. *Cornus canadensis* is worthy of a note. It carpets the ground in the same manner as the weed *Anemone*. The little Foam Flower, spreading widely in a sheltered spot, was very pretty.

J. C. B.

**Alstroemerias.**—I noticed the other day some of these beautiful flowers growing in a sloping bed of light and shaly soil that in strength surpassed any that I had before seen. The tallest plant was considerably over 3 feet in height and others were nearly as tall. The many-tinted, delicately-coloured blossoms were just expanding in hundreds and the foliage was dark and abundant. The plants in question had been raised from seed which had been sown in the bed seven years previously, since which time the seedlings had not been touched. Plants were coming up here and there in

the hard gravel path that bordered the bed and also between the interstices of the steps that led down by its side. In my own garden in heavy soil I find them quite hardy, though, having planted the tubers 3 inches instead of 6 inches deep as recommended, I was prepared to lose many during the last winter, and was agreeably surprised to find them this spring none the worse for the damp and cold they had experienced. Still I should imagine that a light soil is capable of bringing *Alstroemerias* to the greatest perfection, and that the plan of sowing the seed in the bed that is to contain the plants is preferable to planting the tubers.—S. W. F., *Torquay*.

**Iris stylosa.**—This lovely Iris, which is invaluable for the scented blue flowers that it produces through the depth of winter, is not always happy in its surroundings. I know several gardens where it merely exists, never flowers, and dwindles rather than increases. I saw last week an enormous clump of this Iris fully 3 feet through growing on a steep slope of light soil facing south, where it seemed perfectly at home. This clump, I was told, flowers very freely, and had been divided many times. In the neighbourhood of Algiers, where this Iris grows wild, it is found on dry hills and beneath the shade of sloping woods, while *I. reticulata*, which also abounds there, loves the neighbourhood of stream and pool. *I. stylosa* should, to be seen at its best, have light soil and be planted on a slope with a certain amount of protection from piercing winds.—S. W. F.

**Sedum spathulifolium.**—This excellent rock plant is a native of North America, and though easy to grow is by no means common. Several plants now in bloom look very effective. The leaves (as the name implies) are spatulate, and although of a fleshy nature, the plants have stood the test of the last severe winter. The leaves are glaucous in colour and are arranged in rosettes; the plant is only a few inches high and of very neat habit; the flowers are bright yellow and appear in loose cymes. Like most *Sedums*, it seems to thrive best in a sunny position.—F. W. M.

## NOTES ON HARDY PLANTS.

**Lewisia rediviva.**—What a fascination to see a number of these flowers open suddenly some June morning as soon as the first glint of sunshine reaches the plants. Last night, as for days before, I had, of course, seen the swelling buds, which in their peculiar fashion rested on their sides on the ground, but for anything I could know they might have gone on days longer, but this morning with a wonderful unison half-a-dozen plants, without any warning that the observer could read, burst their bulky buds and let loose the compressed satiny petals, displaying them in all their exquisite beauty of tints, ranging from paper-white, blush-white, pink, and salmon-pink, and in all cases glistening like glass. The flowers close daily about two o'clock, but for four or seven days they may be seen, preferably in the morning hours; by the time the flowers have done the plant will have shrivelled up to the merest threads, which you might not have seen had you not known that something had existed there but a few hours before. We see this native of the Rocky Mountains is most aptly named *rediviva*, or the Resurrection Plant. It puts on its most beautiful dress as it disappears, not to show itself again until September or October in the form of bristling tufts of succulent grass, and in such state more or less visible all winter.

**Campanula patula (L.).**—I believe this is given by different authorities as of biennial and perennial duration. Anyhow, its pleasing variability and big pendent bells laxly borne on many-branched stems and lasting for weeks make the plant worth a place. The plants I have in mind are from seed brought by a lady from Wildbad. I see the same plants which flowered last autumn are again in bloom. I never saw a British form so attractive as this; still one hardly knows what our native plants are capable of as decorative flowers until they are

well cultivated. I never was more struck with this fact than in the case of masses of *C. rotundifolia*. I only hope *C. patula* may prove perennial, but if it does not it seeds freely, only tree-seeders and self-sowers come where they are not wished as practically to constitute themselves weeds.

**Hypericum aureum.**—This is, I believe, a new plant, and the name may seem a poor one for a *Hypericum*, the essential colour of whose species is yellow; but here the colour may be said to have special reference to the margins of the leaves, which are golden, and also to the deeper yellow of the stamens in relation to the other parts of the flower, and this is all the more remarkable when we see the splendid massive stamens constitute the chief part of the flowers. The petals are comparatively small, hence the distinct aspect of this species. I find it most reliably hardy, and it vies with the kind called *H. Moserianum tricolor* for bright foliage colouring in the autumn.

**Cytisus schipkænsis.**—I spoke of this last year, basing my remarks on a specimen flowered in the cool greenhouse. I have now to speak of a specimen grown in the open air and stood out-of-doors without any protection all last severe winter. Moreover, my present specimen is on its own roots (not a worked plant) and it gives a totally different idea of its habit, which is prostrate or procumbent; even strong branches rest flatly on the earth. It is now in flower—how lovely and how distinct! The flowers are large, white and arranged in terminal tufts on the ends of all the short twigs. Beyond all doubt this is a shrubby species of the first order for culture in the rock garden.

J. Wood.

*Woodville, Kirkstall.*

## FLOWER GARDEN NOTES.

**PINKS.**—Cuttings of these may be put in as the different varieties go out of flower if it is desirable to increase the stock, and a bed may be prepared at once for them. As previously noted, I am inclined to prefer a bed in an extemporised frame, where they may be shaded for a time if necessary or get the benefit of all the sunshine available should the weather prove dull and showery for some time after their insertion. Soil turned out from pot, pan, and box at the time of planting out summer bedding stuff will do very well for the cuttings of Pinks, Violas, and alpine Phloxes, later on for *Antirrhinums*, *Pentstemons*, the *suffruticosa* and *decussata* section of *Phloxes* as well as for layering a few special Carnations that are likely to be required for pot work. As this soil, if lying in a heap fully exposed to the sun, will probably be very dry, it should receive a good soaking of water after levelling down the day before the cuttings are inserted, previously adding a little fresh leaf soil and sand and incorporating the same with the old potting soil. Some 4 inches of soil resting on a hard bottom are much better for cuttings of all the above plants than to allow a considerable depth; under the latter conditions the roots will ramble far afield and the plants suffer proportionately when they are lifted for removal to other quarters. With Pinks may be planted the large-flowered single *Begonias* (the crimson, scarlet and pink shades). The flowers of the Pinks will be over before the *Begonias* are at their best, but the foliage will form an admirable carpet for the large drooping flowers.

**MARGUERITES.**—In the note on "Flowers at Gunnersbury House" I see the statement made that Mr. Hudson keeps the leaf-boring maggot, so detrimental to the preservation of clean, healthy foliage on the large-leaved *Marguerites*, in check by the aid of Richards' vaporiser. Does this mean oft-repeated doses to ward off the attack of the fly, or that the maggot itself once established is destroyed by the vaporiser? I have been led to the query because the large-flowered varieties, both white and yellow, used to enter rather largely into vase and window-box arrangements, but I was obliged to discard them, as long before the end of the season the foliage presented a most

unsightly appearance. The small-leaved variety is not so susceptible to the attack of the maggot, and is used for the centre of vases or as a back row for boxes, edged with a nicely contrasting trailing plant, as Fireball *Tropeolum*, Mme. Thibaut Ivy-leaved *Pelargonium* or the trailing blue *Campanula*. For large vases or boxes, alternate plants of a dark *Fuchsia*, such as *Abundance*, may be associated with the *Marguerites*. I notice complaints respecting the very indifferent appearance of the autumn-flowering perennial *Marguerite*, *Chrysanthemum maximum*. It wants annual removal; at least, this is my experience with it on a light, dry soil. The old stools should be lifted clean out at the end of each flowering season, and the strongest bits selected and replanted, doing them thoroughly well. Writing of *Chrysanthemums* reminds one that where clumps or beds of the summer-flowering varieties, whether pompon or Japanese, were planted, they are likely to want a little attention, if the hot, dry weather continues, in the shape of a mulching of good manure and a thorough soaking of water. I should like to extend this soaking so that it includes the whole of our herbaceous borders. The ground is getting very dry, and all plants, especially moisture-loving subjects, are beginning to look the worse for the drying out at the root and the daily strain imposed by a hot sun. I am glad to note the appearance of shoots—weak numerically and lacking vigour, but, nevertheless, very welcome—on our big stools of hardy *Fuchsias*, that have been in their present quarters many years, and which I thought had succumbed to the exceptional cold of last February. I shall run no risk again, but mulch the stools heavily at the approach of winter. Nearly all the *Gypsophila* is also on the move, and as there will be a considerable difference in the time of flowering between the early and late clumps, the season will be proportionately extended. This is getting a very familiar plant. At the majority of summer shows it enters very largely into nearly all arrangements of cut flowers.

**FLOWERING SHRUBS.**—The best season of the pleasure grounds—so far as a blaze of colour is concerned—has departed with the decline of *Azaleas* and *Rhododendrons*, which had in their turn followed hard in the wake of the displays furnished by *Ribes*, *Forsythias* and *Weigelas*, but there are some interesting things still in flower. *Chionanthus virginicus* is one of the most delicately beautiful things we have in hardy shrubs, and with not too bright or prolonged sunshine lasts in flower a long time. Now that its value as a forced shrub has been demonstrated it should find its way into many large conservatories early in the season, and from thence be consigned to the shrubby border. *Colutea arborescens* is a shrub not widely known. It is seen to advantage just at present in a large border formed at the end of one of the lawns, backed by a nice clump of *Prunus Pissardi*, the latter flanked by two large *Spiraea arifolia*. Nice sprays of the highly-coloured *Prunus* are very acceptable in a cut state to mix with small branches of the *Colutea* with *Kerrias* or flowers of similar hue. A novelty in flower just at present is *Asimina triloba*. By no stretch of the imagination could it be pronounced beautiful, but it is a very remarkable flower both in shape and colour. I noticed several flowers this year of a very intense hue, the shade apparently varying as one turned the flower from side to side, and going off almost to the shade of gold towards the centre. Perhaps the finest object in the shrubberies just at present is the double form of *Deutzia scabra*. I have had occasion before to draw attention to the exceptional beauty of this shrub, and this year all the plants are simply a mass of flower. This, when one gets plants some 9 feet high by as much in width naturally means a very beautiful display, and if one can manage to get something planted fairly close to the shrub that will contrast nicely with it, such, for instance, as *Delphiniums* or *Larkspurs*, the effect is very pleasing. The value of this shrub is enhanced from the fact that, like the varieties of *Ribes* referred to in a previous note, it can be very readily increased from cuttings,

really nice little bushes being furnished by this means in a couple of seasons. The value of the white and rose-coloured double forms of the common *Bramble* for certain positions in the wild garden is now generally known, and one often comes across clumps in situations for which they are admirably adapted and which could hardly be filled more satisfactorily by any other plant. Like another trailing plant—the *Ivy*—these *Brambles* will accommodate themselves to almost any description of soil, although they are seen at their best in deep, rather holding ground, a remark equally true of the common *Blackberry*.

**DAFFODILS.**—Where these are naturalised in pleasure grounds the foliage will be found to have come to an early—it is to be hoped not premature—decay, and if in spots where it and the *Grass* growing somewhat long amongst is apt to be objectionable, there will be no harm now in running

exceptionally severe one, but the *Lobelias*, which remained totally unprotected in the open bed, came through the ordeal scathless. I am convinced that in some gardens the plants may be left out with impunity, while in others, do what you will, it seems well-nigh impossible to keep up a stock. I speak feelingly as to the latter phase, as formerly in a sheltered garden with light soil I could not induce the plants to survive the winter in the open. I would advise growers of these *Lobelias* to try the various methods recommended for preserving their stocks, viz., leaving the plants undisturbed where they have flowered and protecting with a light mulching—leaving them in the same manner, but without protection—lifting the clumps, storing in cold frames, and dividing in the spring—dividing in the autumn, growing on in single pots in heat until well started, and then placing in a cool greenhouse:

they will then soon discover which process is the most successful in their locality, and can adhere to that.—*S. W. F., Torquay.*

**Sedum kantschatcicum.**—Though introduced from Northern Asia many years ago, this handsome rock plant is not seen in gardens as often as it deserves to be. It is now in full bloom. The flower-stems are semi-prostrate, bearing an umbellate cyme (4 inches or 5 inches across) of bright yellow flowers with orange-coloured anthers. The individual flowers are not much more than half an inch in diameter, but being combined into a large cyme they are very effective. The plant is very easily grown and should be in every rock garden.—*F. W. M.*

**Propagating Pinks.**—The season of flowering of these charming as well as useful and in many instances sweetly fragrant flowers will soon be over, and as soon as the blooms are past, preparations may be made for increasing the stock. Many who grow these plants largely rely in the main on division of the roots later in the year, and particularly so of the commoner kinds. Divided plants flower quite freely, it is true, though the individual flowers are smaller than those borne on plants

The flower garden at Offington. Engraved for THE GARDEN from a photograph sent by Miss Gaisford.

the scythe over it and clearing away. I have mentioned the *Daffodils* because if it is deemed advisable to extend their naturalisation, a decision must be come to ere long as to the varieties to be introduced and the most suitable sites; also if they are likely to be required for cutting, to so choose the sorts as to provide a season at once lengthy and well sustained. *E. BURRELL.*

*Claremont.*

**Herbaceous Lobelias.**—Referring to the subject of wintering herbaceous *Lobelias*, anent which eight notes appeared in vol. xlvii. of THE GARDEN, I may state that the plan of leaving them untouched in the open border has again answered admirably. Not one of the clumps is dead, but all are throwing up strong growths. As I pointed out (p. 529, vol. xlvii.), only one of the many writers who took part in the discussion advocated leaving the plants *in situ*, and that one recommended protection during the winter in the form of a few inches of *Fern* or rough leaf soil. The soil here is heavy and the winter has been an

from cuttings. Stock raised in the latter way is generally marked by increased vigour together with a compactness of the tufts not usually to be found in divided plants. Few plants are more easy of increase by cuttings, and the flowering over, plenty of material will be obtainable, so the work may be taken in hand at once. The simplest and safest way to ensure success is to strip the shoots from the tufts with a heel attached, and without further preparation or ado, insert them firmly in sandy soil. Where only a few dozen are needed a shady corner will suit them well, but if a quantity is required it will be best to give the cuttings the protection of some lights. Covered by these and shaded rather lightly, the cuttings, if kept moist, will root in about three or four weeks. During this period they must not be kept too close or too wet. I prefer when watering the cuttings while in frames to apply the water overnight, giving a good soaking, and allow the lights to remain off all night, replacing them about 8 a.m. the following day. Treated in this way the losses are very few. When inserting the cuttings

a fair amount of room should be given so as to permit of growth. Better still if as soon as rooted the young plants be transplanted into small nursery beds in good soil 6 inches apart each way, as by so doing fine bushy little tufts will result in a very short time. The young plants prepared in this way make nice presentable subjects for sale, while for potting up in early autumn preparatory to forcing they are all that could be desired, and in every way more satisfactory than divided plants. The side shoots are earlier produced by removing the central growth when the plant is established.—E. J.

## KITCHEN GARDEN.

### THE EXHIBITION STATUS OF THE TOMATO.

DOUBTLESS to many it may be thought strange that any dispute should take place over the status of the Tomato. To them the question is one they have settled for themselves. Given only plenty of Tomatoes, and they are eaten ripe and uncooked with the same avidity that they are partaken of cooked. Were the Tomato essentially a sweet fruit such as is the bulk of what we term dessert fruits, it is doubtful whether it would be so generally acceptable in its various cooked forms as it now is, yet the absence of that sweetness and flavour peculiar to most dessert fruits in no way detracts from its consumption in a ripe, uncooked state: indeed, there can be no doubt but that such consumption is rapidly increasing. Ordinarily, this beautiful, if not delicious, fruit is classed as a vegetable. It is the victim to some extent of indifferent origin and gradual development. Starting with very indifferent examples that were not at all attractive uncooked, naturally the Tomato fell into the vegetable groove or rut. It was regarded only as a sauce product or an ordinary vegetable accessory to dinners, and hence its long recognised vegetable status. Its next development might be said to have been found in its exaltation to a very pleasant salad element—for Tomatoes have been for some time identified with salading—and to-day form a common feature or accompaniment. Still, this latter association only helped to retain the Tomato amongst vegetables. During the past few years, however, it is most obvious that these fruits have taken a higher position. The world has so far recognised their excellences in a ripe raw condition, that they are consumed largely in that condition as ordinary accompaniments to meals, and even partaken of as refreshment at odd times.

It is this development of a most interesting and beautiful garden product that has caused the dispute as to the exhibition status of the Tomato to arise. It is a question much more easily raised than satisfactorily settled. Apart from their undesirability for ordinary sale, there seems to be no limit to the size to which Tomatoes may be grown for cooking, provided the fruits are firm, fresh and of good form. But fruits of these huge dimensions are very objectionable for consumption at meals in a ripe and uncooked state. To meet this latter requirement we have produced in great abundance small fruited sorts of various shapes and colours most of which are singularly adapted for dessert use, but would be almost useless for cooking. Naturally, even in connection with large-fruited sorts, a line is drawn when forms of consumption differ. The largest and most ungainly go to the kitchen, the small and handsome fruits to the table direct, and in this way again the status of the Tomato is clearly shown. Practically we cannot get away from the fact that, having regard to its peculiar nature, a fruit of the most perfect form and beautiful colour, allied to soft, luscious, if not rich-flavoured flesh and exceedingly thin rind, it is as much entitled to rank as a dessert fruit as any other recognised fruit is. Indeed, it is very absurd to assert that it is not or cannot be such in face of the fact that it is already so regarded and consumed by millions of people.

But then there is to be remembered the fact that by common consent hitherto Tomatoes have been shown as vegetables, and such common consent cannot be ignored. To refuse to them their old position in vegetable collections would be as fatuous as it would be unwise; indeed, there is for such course no reason whatever. But then it will be said Tomatoes cannot be regarded as both fish and flesh, as both fruit and vegetable. To that it may be asked in reply, Why not? What earthly reasons are there why they might not be so regarded? Amongst vegetables on the exhibition tables they, when good, occupy a high, indeed a very prominent place. Amongst fruit, of course they come low in position. It is so far a fact as to be undeniable that the Tomato, more than any other product we have, forms a connecting link between fruits and vegetables, whilst they have botanically as good a title to be termed fruit as anything else that is grown.

In a matter that creates difference of opinion it is so natural for many who are yet undecided to turn to the Royal Horticultural Society for a proper lead. That is a judicial position from which that body may well shrink, although not lacking courage. It would almost seem as if a judgment already had been given, because the council did last year, as it has again this year, create classes for Tomatoes at the great fruit shows at the Crystal Palace, and thus have placed Tomatoes in the category of fruits. That position would seem to be emphasised by the fact that in the vegetable show schedule, to take place at Chiswick in September, Tomatoes are not mentioned. Still it will not for one moment do to assume that it is proposed to make Tomatoes into fruits absolutely and to ignore them as vegetables. Their omission from the Chiswick show is perhaps an oversight only, perhaps determined because included in the Crystal Palace schedule. However, the real mind of the society on this interesting matter will probably be clearly set forth later when the new code of judging is formulated, and no one need be surprised if therein Tomatoes are found to occupy the perhaps anomalous, yet imperative, position of being regarded as both fruits and vegetables. A. D.

**Rhubarb Hawke's Champagne.**—So popular has this early and richly-coloured Rhubarb become in the market, that it always obtains a higher price than any other, thus proving that colour is an important consideration. Later sorts have been very much a drug this season owing to the immense crop of Gooseberries everywhere and the early period of their maturing. The run on Gooseberries, however, serves to show the importance of having varieties of Rhubarb that are very early as well as of rich colour, and so far Hawke's Champagne seems best to meet these requirements. It is almost surprising to find how rapidly any variety is increased in the market gardens, but good ground and high culture soon create wonders. Then frequent dividing and transplanting into freshly manured ground also materially tend to precocity.—D.

**Dwarf Peas.**—All Peas in gardens have been experiencing a very trying time during the long drought which has been so marked in many districts. Especially have the taller varieties been distressed from lack of moisture, as these, but the taller especially, have to materially exhaust the soil resources of food and moisture before podding commences. When grown very thinly, as is now in good gardens more the rule, and sown in rows very widely apart, there is less trouble. If the ground has been deeply trenched or otherwise specially prepared by deep working and liberal manuring, the Pea plants may get over their trouble fairly well. But in myriads of gardens Peas, and especially tall ones, are still grown far too thickly, and on ground that has been only ordinarily prepared. No wonder by the time they commence to bloom the lower leafage is thin or flagging, and the plants are quite incapable of carrying a decent crop. In such case even liberal waterings and mulchings of manure seldom com-

pensate, as the roots are hardly helped and the mischief has been already done. It is during such seasons as the present that sorts that range from 2 feet to 4 feet in height, in which section we have many of the finest quality and abundant croppers, prove to be so serviceable. Being far less exhaustive of moisture than are tall Peas, they can be induced with fairly good culture and thin sowing to carry out their crops fully and to much more freely retain foliage. Frequent overhead sprinklings at night may also be easily given. It is very doubtful whether Peas that range to an average height of 6 feet are more productive from the same length of row than are those which reach to a height of only 4 feet. Even the growing difficulty of finding needful supports to Peas presents another reason of an economical kind why dwarf varieties are generally the best.—A. D.

**Mint.**—This excellent herb constitutes about Mitcham a very important field crop. On one farm alone over 20 acres are grown, but chiefly of the Peppermint, as that is the most useful for distilling. There are two varieties—white and black. The former, however, is far from being white. It is really less dark than is the black, and is the more esteemed because it furnishes the finest or richest perfumed oil. The common Spear Mint is also largely grown, but chiefly for ordinary uses. New beds are made every spring, and old ones seem to be renovated every few years. Much depends on how they stand. The ordinary course of culture consists in having ground very deeply ploughed and manured, well barrowed and levelled, then marked out into lines with what is called a racer, a foot apart. The young growths when just high enough to handle are lifted from the old beds and planted out from 10 inches to 12 inches apart in the rows, and where growth is good the plants form almost a dense mass to cut in August. It is then laid along neatly in rows, and later gathered up on mats carefully and carried into the distilling houses, where the oil is extracted. The refuse, because containing potash largely, forms good manure.—D.

### EARLY CAULIFLOWERS.

**MR. TALLACK** (see p. 421) does not recommend Waleheren for earliness, but Early London. As I grow Cauliflowers in considerable quantities I have at some little trouble gone into the matter and tested the earliness of various kinds. Early London in a trial at Chiswick last season was very much like Waleheren, but it must be explained the trial was not for earliness, but to test varieties. It was soon seen, however, which was the earliest; this was the Erfurt type, a variety I would strongly advise Mr. Tallack to try, as this season our Early Erfurt is all one could wish. It is also known as Dwarf Erfurt, and is really a splendid type of Cauliflower, not at all small for private gardens. As regards marketing, I cannot speak, but for earliness Early Erfurt is superior to all others. I think there must be several varieties of the Erfurt, as that I grow is large enough for all purposes, short in stem, and with a very compact flower or head; whereas Mr. Tallack says varieties of the Snowball type are generally too small for market. This brings me to the question of synonyms, and to show how the Erfurt section varies and is classed, I give the Chiswick classification in full. Early Erfurt, Early Short-leaved Erfurt, Dwarf Erfurt, Small leaved Dwarf Erfurt, Earliest Dwarf Erfurt, Dwarf Mammoth Erfurt, Snowball, Early Snowball, Early Taranto. These are all classed together as one type and described as follows: Plant dwarf, leaves small, medium-sized heads, from 6 inches to 12 inches in diameter, frequently larger, close, pure white, distinct, and the earliest variety. I should say mine are labelled Dwarf Mammoth Erfurt and are double the size named at this date (June 18). The crop is nearly all cut, the plants being autumn sown and wintered under hand glasses. Early London is known under the following synonyms: Stadholder, Large Early, Second Early, and Middle Late Dutch, and at Chiswick all these were, in my opinion, inferior to the Erfurt as regards earli-

ness. Strange to say, the Walcheren is included as synonymous with the Early London section; whereas my Walcheren is more compact, dwarfer, and equally as early as Early London. The last section is described as medium sized, tall, head 8 inches to 12 inches in diameter, solid, and of excellent quality, but with the following addition, the plants vary considerably, according to selection. My Walcheren is quite distinct from Early London—doubtless a better selection. Selection is an important point in vegetables of any kind, as it takes years to get a true stock. Considerable advance has been made by the introduction of the early kinds, of which the Erfurt is the type. The same remarks apply to the later section, such as the Autumn Giant and Autumn Mammoth types, though I do not favour a huge, coarse Cauliflower in any shape or form, nor am I in favour of those small kinds which button prematurely. Doubtless it was these latter kinds Mr. Tallack had in his mind when describing some as too small. The true Erfurt section is large enough for all purposes when well grown, and Mr. Tallack should give it a trial if he can get a good stock. I am sure he would find it useful and reliable. Some twelve years ago I had a wretched strain of Early London, and have not grown it since. I expect this variety varies quite as much now as then. Mr. Tallack may have a good type, as he says it must be grown for its earliness. I have had Erfurt sent for Walcheren, and *vice versa*. G. WYTHES.

**Turnip Orange Jelly.**—"J. C." does well on p. 421 to call attention to this Turnip. It is quite one of the best for autumn and winter use. At the Chrysanthemum show in Edinburgh at the middle of November last year it was shown in almost every collection of vegetables, and that is saying much for it, as collections there are perhaps more numerous than at any other autumn show in the United Kingdom. The uniform size, clear skin, and perfect shape of the Orange Jelly Turnip much impressed me.—E. M.

**Early Cabbages and other greens.**—At p. 398 "A. D." does well to point out the dearth of greens or good Cabbages during May, and the persistency with which market growers adhere to the large, coarse varieties with much leaf that are later than the small-hearted varieties. I suppose it is difficult to get over the preference for mere size in everything marketable, and thus the large kinds are more grown. I know that retailers have a decided preference for the large-leaved Cabbage with a tie round them to make them look presentable. A dearth of greens could readily be prevented if more attention were paid to the dates of sowing, planting out, and other details, and many large growers could take a lesson from private growers in this respect. I do not see where the loss would come in by planting small kinds, as so many can be grown on a small space. Again, the new Kales of the Messrs. Sutton would prove valuable market vegetables in such severe winters; their arctic Kales are frost-proof. Sown late they soon make good plants. In seasons when there is plenty of Broccoli they may not be so acceptable, but then they may be used before the Cabbage or Broccoli turn in.—G. W. S.

**Transplanting Parsley.**—This is necessary in order to ensure a plentiful supply during autumn, and also to furnish roots for lifting in October and planting in cold pits and frames for winter supply. Where through absence of rain the ground is hard and dry, a thorough soaking after levelling and raking must be given. If a narrow border slightly shaded by espalier trees can be given, so much the better; or if not, shading by evergreen boughs must be resorted to. Use great care in drawing out the young plants from the seed rows and plant with a trowel, firming well and afterwards watering home. In gardens where wireworm is troublesome prick in some soot and burnt refuse. Gas-lime must not be used where planting has to be performed immediately. Where a cool pit can be spared, a transplanting

into it may well be made, this of course doing better as a rule than plants removed in autumn. In transplanting Parsley in the open garden select also a small square plot, over which a two or three-light frame can be placed in November, as it is next to impossible to have too much for garnishing and general kitchen work during the winter months. I always sow here about the middle of July for a spring supply, protecting the young plants in winter by a frame. This sowing soon makes large fronds fit for use in spring, whereas if sowing is deferred till March or April the produce is not fit for use till mid-summer. Dobbie's Extra Curled Parsley and Veitch's Curled are capital kinds.—J. C.

**Lifting early Potatoes.**—The earliest Ashleaf Potatoes growing on south and other warm borders if ripe may now be lifted and sorted, eatable tubers being stored in a cool dark place and the seed treated similarly. Some advocate leaving the tubers out in the open air for a week or ten days to become green from the exposure to sun and air, supposing that a more thorough ripening is thus effected and a stouter and better start guaranteed in spring. I have tried this plan and could never see any real difference between them and the tubers which were housed as soon as dug. The ground hitherto occupied by these early Potatoes may now be broken down, and after having a good watering be utilised for sowing Lettuce and other quick-growing, shallow-rooting things, being then ready for such crops as Coleworts at the end of August.—C. N.

**Frost in Notts.**—Last year we thought May 20 late for frost, that being the date of the disastrous one, which gardeners will long remember. This year we escaped in May, only to have the things cut down in June. On the night of Friday, the 14th, frost of a severe nature visited this neighbourhood, cutting down Potatoes, Scarlet Runners, and Dahlias, and checking other tender crops. Within a radius of eight miles 6, 7, and even 8 of frost were registered, and on our own premises ice could be found on gates and rails in early morning. This is a very serious matter, and must materially affect small market growers who depend on their gardens for a living. Fortunately our own garden lies rather high, and the soil is dry and warm, thus we escaped the damage which those around us received. It would interest me to know if this frost was general.—J. CRAWFORD, Newark.

#### TOMATO NOTES.

ARE old or comparatively old varieties of Tomato more subject to disease than those of recent introduction? This query, I think, many will answer in the affirmative. My experience is decidedly in favour of discarding the old sorts, as they are so prone to disease in some of its many forms; consequently they are less productive, and the fruit from these diseased plants is neither so well formed nor good in flavour as from clean healthy plants. Up to the present date (June 18) we should naturally conclude that the season had been specially favourable for Tomato culture under glass, but, on the contrary, I never recollect so many inquiries on how to conquer disease in different forms. The most general appears to be *Cladisporium fulvum*. Several old market growers state they never had so violent an attack as this year, and after trying various remedies (so-called) have fallen back on the plan of removing the infested foliage and encouraging new growth. The black spot (*Sporocybe lycopersici*) is more than usually in evidence in some gardens, but I believe this may be practically ousted by keeping the hot-water pipes warm on dull or cold days, also at night, and maintaining a dry, warm buoyant atmosphere in the house continually, which will do much to keep the *Cladisporium* in check as well. Another disease that is more difficult to deal with is the one that suddenly attacks a healthy-looking plant, and in a few hours the foliage droops and the plant is completely done for. I had a few plants this spring thus attacked.

These were at once pulled out and burnt, and no further signs of the disease have appeared. One cause of disease not sufficiently known is, I think, that of sudden changes from dryness to wetness at the roots. Plants in pots or in shallow borders when full of vigour absorb a great quantity of moisture and quickly become dry at the roots, unless given close attention, which is not always possible in these days of reduced hands; and, judging from close observation, the repeated changes from dryness to the reverse are prime causes of disease. The white fly (*Aleyrodes vaporariorum*) is occasionally very troublesome, messing the fruit and materially weakening the plants. Fortunately this pest is easily destroyed, the recipe for which I am indebted to Mr. Iggulden, who stated in one of the horticultural papers (I forget which) some six or seven years ago that flowers of sulphur mixed with milk and painted on the hot-water pipes would effect a cure. I immediately put the advice in practice, with such excellent results that no white fly has appeared since.

Many Tomato growers consider that natural manures promote a growth that is liable to attacks of disease more readily than plants fed with chemical fertilisers, and I believe they are correct as proved from actual experience. Unfortunately, many gardeners are unable to obtain these chemical fertilisers, as some employers object to purchasing the same while there is plenty of natural manure to hand; consequently one has to make the best use of the materials at disposal. On a light soil I can strongly recommend the following mixture as a really good manure for Tomatoes: 1 lb. of nitrate of soda, 1 lb. of muriate of potash, or failing that 3 lb. of kainit and 3 lb. of superphosphate, mixing the whole thoroughly together and applying at the rate of 1 oz. to each super yard of border, taking care that none of the mixture falls on the foliage or fruit, as it is apt to scald either if it falls thereon. The above dressing may be given about once a fortnight to plants in full bearing. The effect will not be so apparent in the growth as in the rapid swelling and size of the fruit, together with the free setting of the trusses as they form on the plants. Fish guano is another good manure, giving satisfactory results, but has not such a weight-giving effect on the fruit as the preparation named. Amongst natural manures the liquid made from sheep manure has few if any superiors, as it is a reliable fertilizer without the burning character of the drainings from stables or cattle sheds. Pig manure is strong, but on the only occasion in which I employed it as a mulch I found that a quantity of the plants died from the attack of an insect at the roots resembling eel-worms, which no doubt bred in the manure, as I have had no similar attacks before or since. Amongst new or comparatively new Tomatoes that are cropping freely with no signs of any disease the undermentioned are the best. Early Ruby is a very early sort, the plants commencing to fruit almost close to the soil, and the produce ripening about a fortnight before any other variety sown at the same time and grown under exactly similar conditions. Some of the fruit is of very good shape, while others are corrugated, but for home use or market it is valuable for its prolific habit and earliness. A variety that I received from Messrs. J. Carter and Co. named Canadian Express is the most profuse cropper that I have grown; it follows Early Ruby in ripening its fruit, which is large, slightly corrugated, and on light soil the trusses are borne in such profusion that they overlap each other on the plants. Frogmore Selected follows the above in ripening, but I must admit being disappointed with this variety; it may be that the soil or my mode of culture is unsuitable. Whatever the cause is the plants are not sufficiently fruitful to warrant my growing it another season. Duke of York was only a day behind the last-named in ripening its fruit, and what a grand fruit it is; the shape, colour, weight and general appearance are so good that a fruiterer who purchases largely informed me that he would give a penny per pound more for Duke of York than any other variety I sent him. In addition to the good points named it is also an

excellent bearer. Polegate is another fine main crop variety, possessing a short-jointed sturdy habit, well set with moderately sized trusses of fruit, and I think likely to become a reliable market sort. Carter's Market Favourite is a variety that I have not grown, but when at Maindiff Court Gardens, Abergavenny, recently I saw it in splendid form, the plants being covered with handsome fruit of a size very suitable for market. Mr. J. Nowell, who has charge of those gardens, states that it is one of the most profitable Tomatoes in cultivation when done well, and judging from the appearance of his plants they confirm his statement. W. G. C.

**Pea Criterion.**—This fine Pea fully deserves all the praise that has from time to time been given it. It is the summer Ne Plus Ultra, growing and yielding well in hot weather and on sandy soils. The colour and flavour are irreproachable, and it continues to bloom and pod over a long period. Criterion ought certainly to be grown by all to whom quantity and quality combined are an object.—J. CRAWFORD.

**The Pea crops.**—The present season is an unfavourable one for Pea growers for market. The early spring was so unfavourable that the earliest crops were kept back, while the second sowings, influenced by the protracted drought, did not grow to their normal height, and are podding almost simultaneously with the first sown lots. Thus the markets are glutted for a short time, prices rule low, leaving but little profit for the grower after deducting rent and labour. Even on cool, moist lands Peas look yellow and unhealthy on account of the cold winds, which have prevailed at intervals for many weeks. Pea growing for profit now-a-days is much more uncertain than formerly, when heavy crops not only paid the grower, but found lucrative employment for many poor people.—J. C.

**Early Cauliflowers.**—I was always under the impression, and which appears also to be the opinion of Mr. J. C. Tallack (p. 421), that Early London is an earlier Cauliflower than Walcheren. Judge, therefore, my surprise in looking over the report of the trial of Cauliflowers at Chiswick last year and published in the last volume of the Royal Horticultural Society's Journal, that Early London and Walcheren are given as synonymous. The Walcheren as grown by me is certainly a little later, although this season not to such a marked extent as other years during duller and moister weather. The leaves have a more curled appearance, and it is also a better hot weather Cauliflower than Early London. Possibly some other correspondents can give a little explanation. Autumn-sown Cauliflowers have turned out capital this season, and certainly in advance of any sown at the turn of the year. The plants are altogether stronger and better able to withstand the dry and hot season. Plants raised from seed sown early in the year require a lot of looking after, and I cannot see where the saving comes in either of labour or time as some people suppose there is over autumn-sown plants.—A. YOUNG.

**Radishes during hot weather.**—Where a supply of Radishes has to be maintained throughout the summer and autumn months there is often a difficulty in keeping it up during a hot and dry season. Grown on poor soil and in too exposed a position Radishes are tough and hot. Having a regular supply to keep up I give a little more attention than ordinarily bestowed on Radishes. Too much rank manure is not good for them, the quality not being nearly so good as from a bed which is mainly composed of rich soil. An east border is the best position for summer and autumn Radishes. How I manage is to prepare a good heap of old potting soil, burnt refuse, leaf-soil, and some spent Mushroom bed manure, the whole being spread to the depth of 3 inches over the extent of border to be devoted to this crop for a season. The seeds should be sown thinly in drills, and during dry weather be kept well watered. Manure water should not be used. There should be no set time to finish sow-

ing in the open. Last year, on account of the weather being mild up till Christmas, we had daily supplies from the open air till that period.—A. YOUNG.

## TREES AND SHRUBS.

### LEMOINE'S NEW PHILADELPHUS.

A FEW years ago we looked upon the little Philadelphia microphyllus from Colorado as being quite an exceptional addition to a genus which abounds in so-called species and varieties too much alike. P. microphyllus is a pigmy compared to any of the others and its crowds of white blossoms have not that heavy, and to some disagreeable, odour which most Mock Oranges possess. It could not have been long after this little plant was first brought to Europe before that keen hybridist, M. Lemoine, of Nancy, secured it for operating upon, for we see to-day, in the beautiful hybrids that he has given us, how prompt he must have been. He, no doubt, saw that by mingling the dwarf and free-flowering habit of P. microphyllus with that of the tall, larger-flowered species like the common P. coronarius, a beautiful progeny would be the result, as most certainly it is. The three or four hybrids that I have just seen for the first time are a revelation to me. They are all much alike, so that one description will apply to all. The growth is erect, remarkably so, and each shoot is wreathed with pure white blossoms as large as those of the common Mock Orange from the base to the tips of the shoots, which are from 2 feet to 3 feet high. I have only seen the plants in the collection at Kew, but I do not see any marked difference between those named Lemoinei, Lemoinei erectus, Gerbe de Neige, Boule d'Argent, and Candelabra, though these may, of course, be quite distinct when more established. In great perfection may be seen a mass 10 feet through of P. Lemoinei in the arboretum. Every shoot is a sheaf of white bloom and buds, with just sufficient foliage to serve as a foil. One can see the mass of white 100 yards off, and near it there is a soft and exquisite odour like that of a passing barrowful of Pineapples. It is the most glorious new small shrub I have seen for years and is sure to become popular. It lasts a long time in bloom, for weeks, I might say, is not particular about soil or site, and has not flinched, I am told, under the cold of the last arctic winter. Those who love hardy flowers should see this new-comer and the hosts of beautiful plants that make Kew so full of interest just now to those who have eyes to see and hearts to appreciate and enjoy.

Kew.

W. GOLDRING.

**Erica ciliaris alba.**—This dwarf growing hardy Heath, just now giving a profusion of its pure white blossoms, is very showy, and deserving of extended cultivation where the natural soil is favourable to its growth. Around the edge of a Rhododendron bed or border or at the foot of tall growing Kalmias is a suitable site for planting it. Like the bulk of low-growing Heaths, this is easily increased by dividing the roots in early spring.—E.

**Pterocarya caucasica.**—We have a very fine specimen of this tree, and though not reaching the dimensions named by Mr. Burrell, it makes equally rapid growth. Some young trees planted a few years ago are now telling objects in the landscape, and I am surprised this beautiful tree is so uncommon, as it does so well in a fog or smoke-laden atmosphere. I carefully read the note alluded to on p. 424 to see if the fine specimen named was near water, as this tree delights in a moist situation, being a gross feeder. Ours is partially in water, and throws up a great number of suckers. I can well understand the roots going in search of food and moisture, as the great amount of foliage must require a lot of support. I cannot reply to Mr. Burrell's query as to its behaviour in its natural habitat, but it cer-

tainly is fond of moisture. Apparently in this country the tree grows quite as large as in the Caucasian range. Its height there is given as 20 feet to 40 feet. Our tree is taller, very healthy, and one of the most ornamental.—G. WYTHES.

**The Guelder Rose as a water plant.**—Though the common Guelder Rose, or well named Snowball Tree (*Viburnum Opulus*), is also known as the Water or Marsh Elder, yet it is seldom that one meets with it grown in lakes or streams. I found, however, a fine specimen the other day growing and blooming most profusely in a small lake of very cold spring water. The plant was almost 6 feet high and looked as much through, the very picture of health, and smothered with its flower snowballs. In this lake was a small island, and this fine plant was so low down on one side of the latter as to be inaccessible either from the island or the mainland. It was seen in the first week of June, and its roots had evidently been submerged all winter, possibly for years, as the second peculiarity of the spring that furnishes the lake is that the supply of water is as constant as it is cold. Perhaps some readers of THE GARDEN will give their observations and experience as to the growth of other species of Guelder Roses in water, such as the common Wayfaring Tree (*Viburnum Lantana*), whose green leaves glow with a deep red or fiery scarlet in the autumn, and the American Wayfaring Tree (*V. lantanoides*), with finer foliage, fruit, and berries than the British Wayfaring Tree. Other species worth trying in water, wet places, or swamps would be the Sheep Berry or Sweet Viburnum, *V. Lentago*, *V. Fortunei* or *macrocephalum*, with large flowers and leaves, and the variegated-leaved and other varieties of the common Guelder Rose (*V. Opulus*). The *V. odoratissimum* is said to have the scent of *Olea fragrans*, and if so deserves the best place that can be found for it in the choicest garden or shrubbery or cool greenhouse, as it is little more than half-hardy. *V. plicatum*, though fairly hardy, is also invaluable in pots for anticipating in cool conservatories the beauty of the Guelder Roses.—D. T. F.

## GARDEN FLORA.

### PLATE 1020

#### NEW SINGLE CHRYSANTHEMUMS.

(WITH A COLOURED PLATE OF C. PURITY AND C. DISTINCTION.\*)

THE coloured plate shows two new single varieties raised by me at the Earlswood Nurseries, Redhill, Surrey. Purity was distributed in 1893 and 1894, when I predicted it would become one of the most popular varieties. Last autumn it was awarded four first class certificates and was exhibited in nearly every collection of singles at the various shows. Distinction is really better than Purity, having bold thick broader florets and the colour is very rich. Unfortunately, up to the present the old stool of last year, although it still retains the foliage, has not furnished a cutting. Should it persist in this character, one of the very best single kinds ever seen will be useless for gardens. Single Chrysanthemums are so useful for decoration as cut flowers, that it is no wonder they are beginning to be cultivated to some considerable extent. They furnish nearly every colour for the dull winter months that the Shirley and Iceland Poppies, Gaillardias, Harpaliums and Marguerites supply in the summer. They do not require disbudding, for their chief beauty is in their graceful sprays. Some varieties can be cut with stems 2 feet long bearing flowers

\* Drawn for THE GARDEN by H. G. Moon, in the Earlswood Nurseries, Redhill, Dec. 1, 1894. Lithographed and printed by Guillaume Severeyns.

their whole length, and if the old stems are left they throw out a number of small shoots below which give a succession of flowers on to February. Some of the best small flowering varieties are Scarlet Gem; Miss Mary Anderson, white; Treasure, yellow; Emily Wells, pink; Earlswood Terra-cotta, and Golden Bronze. Of the larger flowering and medium sized, there is a great choice. Rev. W. E. Renfrey, Mayblossom, Foxhunter and Charman's Joy are scarlet or crimson; Nora, Mrs. D. B. Crane, Miss Grace Rennie and Rose Pink are all pink; whilst Purity, Lizzie Mauwaring, Virgin Queen, Jane in whites, and Admiral Sir T. Symonds, Arthur Horne and Distinction in yellow; with Earlswood Terra-cotta, Esthetic, Lady Churchill and Salmon as a selection of the best. For pot plants the best are Miss Rose, Scarlet Gem, Gus Harris, Earlswood Terra-cotta, and Miss Mary Anderson. These should be rooted in March, pinched twice, and then grown on in 5-inch or 6-inch pots. The general collection for cutting in sprays should be propagated in January or February, pinching twice and allowing ten or twelve shoots to grow to each plant. They like good rich soil as well as the general collection of Japanese and incurved, but they need not be attended to so closely. I generally put one stake to each plant and loop the branches to it.

W. WELLS.

## THE WEEK'S WORK.

### THE KITCHEN GARDEN.

**GENERAL ROUTINE WORK.**—The past few weeks, owing to absence of rain and frequent parching winds, have afforded an opportunity of thoroughly eradicating weeds amongst all growing crops. Where rain has fallen, no time must be lost in going through all growing crops now in their infancy and hand-weeding the rows or beds. Seedling Nettles are a pest in some gardens, and unless kept under soon choke and spoil the plants. Onions, Beet, Parsnips, Salsify, and Scorzoneria, also seed beds of very early Endive, come especially under this heading.

**MULCHING.**—I have already advised this in the case of earlier crops of Peas, Beans, and kindred subjects, successional crops must now have attention in this matter. All have not time for this work, but the practice is beneficial from every point of view. In many gardens where vegetables are forced on hotbeds ample material for mulching purposes will now be obtainable, and nothing forms a better mulch than old, exhausted forcing beds, and there is always a certain amount of nourishment left in the material to be washed down to assist the roots. Peas, Broad and even French Beans, beds of early Seakale for forcing in November, Scarlet Runners, and even spring-sown and Tripoli Onions respond quickly to a mulching, the same retaining the moisture communicated by rain and preventing undue evaporation. While dry weather continues, a good soaking once a week or ten days may, where practicable, be given. The use also of artificial manure previous to watering not only aids growth, but likewise enriches the ground in readiness for other crops which are to follow these impoverishing ones. Later batches of Spinach as soon as a few inches high enjoy a good mulch as much as anything.

**LATEST WINTER GREENS.**—In many places gardeners are not able to get out their final plantings of late Broccoli, Kales, and other late winter and spring subjects as soon as they would like, owing to the ground being occupied with other crops. Now, however, all speed must be made, as if the plants in the seed beds are becoming large and crowded, a free, vigorous growth after transplanting cannot be expected. Saturate the soil the day previous to drawing out the young plants, or

many of the best fibrous roots will be broken. Draw out good deep drills and soak these also at the same time. Refrain from pulling many plants at a time, placing them in a sieve or basket and covering with a Rhubarb leaf, finally watering home and drawing a little soil from the sides of the drill around the stems of the plants to prevent undue evaporation. If a little rough material can be spread between the rows and round the plants, as recommended for the Seakale and other crops, so much the better. Be sure to plant plenty of the Kales, both Scotch, tall and dwarf, and Asparagus, as these are practically frost-proof and continue to throw out side sprouts from the stems until the earliest Cabbages come in in April or May. Ragged Jaek, commonly grown in the open fields, is also most useful in spring and makes a pleasant change in the dining room. All the foregoing are best put out on firm soils from which other crops, not of the same nature, have recently been cleared. If too hard for the dibble, a crowbar may be used. Another and final planting of Savoys may also be made, but as an exposed situation and dry root run often cause these to heart in before wanted, a north border should, if possible, be selected and a good quantity of rich manure incorporated, firming well before planting. The old Drumhead variety is unsurpassed for this last batch, taking longer to arrive at maturity and not so liable to rot from excessive rains and frosts, its leaves overlapping one another in such a manner as to protect the centres. If Chou de Burghley was sown as recommended at the beginning of May, the plants will now be ready for moving. If put out in rich soil, Chou de Burghley is a most delicious vegetable. Plant as for Kales, allowing 2 feet between the plants and the same between the rows. Prick the small plants out in a moist rich bed and plant out in three weeks' time to give a succession. Chou de Burghley is quite hardy, late plants making headway even in frosty weather.

**LATENT BROCCOLI.**—As second early Peas and Potatoes are cleared off, such valuable late varieties of Broccoli as Model, Late Queen and Methven's June should be transplanted. The same hard root-run is advisable, a small basin being afterwards made round the base of each to hold water. If the ground is not in extra good heart a good broadcast sowing of some approved fertiliser may be given as soon as growth is visible, and again say in a month's time.

**SALTING ASPARAGUS BEDS.**—The present time is opportune for giving a second dressing of salt to the surface of Asparagus beds, not altogether as a manurial agent, but as a weed destroyer. If there is any Twitch growing in the beds, the best—and indeed only effectual—way of removing it is by the use of small hand-forks: the roots are then extracted and further growth prevented. If my advice respecting Asparagus beds given in April was followed, and a mulch of short manure given to those composed of sandy soil and resting on a gravel subsoil, a little artificial manure should be mixed with the salt and afterwards worked in amongst the manure with a rake. It will then be ready for washing down to the roots as soon as rain comes. Much may be done between now and the period when the stems begin to turn yellow towards encouraging strong crowns and a multiplicity of roots near the surface, the best and indeed only guarantee for a productive crop next season. Where beds exist in low situations not over well drained, the use of salt, except in exceptional dry seasons, is not advisable; hand-weeding must in such cases be resorted to. See that the grass from young plants in newly-planted beds is supported by small stakes, or high winds may break it down and a weak stool follow next year. Assist also these young beds with liquid manure.

**BEANS IN COLD FRAMES.**—These, where planted out at the time advised, will now be in flower, and good treatment must be accorded, or the end in view will be defeated. I do not hold with the common practice of allowing the rows to fall one against the other. Rather support them by means of short, stout sprigs. The air and sun will

then penetrate to the interior, and not only a more abundant crop, but one of better quality will ensue. The roots also must not lack moisture or nourishment, especially just at the setting period, and no old pods must remain on to use up the vital force of the plants. Overhead waterings are of great help to French Beans, these being given liberally at eventide, so that the foliage may be enabled to recoup itself after the strain put upon it by hot sun and parching winds. I still find Syon House capital for cool frame work, also Negro Longpod and Canadian Wonder to follow.

**CELERY MAGGOT.**—Owing to a parched state of the atmosphere the Celery fly will be liable to abound early this season. A sharp watch must be continually kept, and on the first appearance of leaf-disfiguration hand-picking must be resorted to, as there is no other remedy, the maggot being between the tissues of the leaf and away from the reach of any insecticide. Occasional sprinklings of soot may, however, ward off the attacks of fly.

J. CRAWFORD.

### FRUIT HOUSES.

**EARLY PEACHES.**—The fruits will now be gathered from trees in early houses, and should red spider have obtained a foothold on the trees during the ripening period, take special precautions to get rid of the pest now. The weather during the past few weeks has encouraged insect pests, it having been necessary to keep the house dry. To get rid of spider the best remedy is abundant syringing night and morning, but even this is not always sufficient. With dirty trees a dressing of soft soap, sulphur, and rain water will be best, well covering the affected portions and syringing freely daily from the third day after applying the dressing. It is also well to place a little sulphur in the water occasionally when syringing in the evening. The roots will also be in condition to receive copious supplies of moisture, and in case the mulch given before the fruits coloured is absorbed, a renewed mulch now will assist root action, keep top-growth clean, and save labour. Give the trees abundance of air, and get the wood as matured as possible, as the more the wood is ripened the better next season's crop. Peaches and Nectarines often suffer after the fruits are cleared, not being given sufficient water. Now is the time to secure good fruiting wood for next season and prevent bud-dropping, so troublesome with early trees. Although I have advised abundant supplies of air, hard forced houses should not be thrown open all at once, but gradually increase the supply of air after the gathering is over. With trees not in a robust condition it is well to allow a little warmth in the pipes in dull weather; this keeps them moving freely and the wood gets better ripened.

**SUMMER-PRUNING OF PEACHES.**—Much may be done now in the way of pruning the early forced trees, and these remarks will apply to those in succession houses as well. By pruning now the main growths will get more room to develop, and the fruiting wood for next season can be more carefully attended to. All wood, or nearly all, which has borne fruit may be cut back to the young growth at the base of the shoot which was laid in. A lot more room is thus obtained, and it can readily be seen how much wood will be wanted to furnish the trees, whilst by regulating the shoots the syringe can readily wet all parts of the trees. As young trees often make much wood, there is no better means of removing any useless growths than by summer-pruning. As soon as the pruning is completed, fire-heat may be dispensed with should the wood be well developed, and the house thrown open to harden the growths. Young trees when tied to the trellis in the winter are often given too little room. Now is a suitable time to give the trees more freedom, loosening ties, and thus preventing gumming and canker, which closely follow restricted growth or damaged bark. In pruning young trees, use the knife sparingly if there is ample room for extension, as

a large space may soon be covered, and the lateral growths springing from the main branches may be turned into good fruiting wood for the next season.

**SUCCESSION PEACH HOUSES.**—The fruits will be ripening, and with abundance of sun-heat very little fire-heat will be required. Peaches given free ventilation are of superior flavour to those grown in a moist, warm temperature. With more air it is well to give moisture freely, and although trees cannot be syringed overhead, all parts of the house can be moistened, as a certain amount of moisture is necessary to get perfect fruits and high colour. The stems of the trees may be damped daily, and any portion of the trees not covered with fruit may be syringed freely. In a previous calendar I noted the importance of going over the trees daily, removing the ripe fruits early in the day, this being much better than allowing any to fall into nets. There is no fear of damage by gathering carefully, and such fruits may be kept good for days in a cool, airy room. Fruits to be sent any distance should not be allowed to get fully ripe, as their weight when travelling—no matter how well packed—bruises the fruits. Trees that are dry at the roots should be given sufficient water to tide them over the ripening stage, and when cleared should be treated as advised for earlier houses, giving a good dressing of manure or liquids to those much exhausted after carrying heavy crops.

**LATE HOUSES.**—The trees are more forward than usual and I have dispensed with fire-heat. At the same time a little extra care is necessary in changeable weather, to ensure the fruits swelling freely. Syringing late trees is necessary twice daily, and there is no excuse for dirty foliage in late houses that can have ample supplies of water in all parts. Feeding and mulching are equally important, as the roots soon dry at this season. The fruits should be freely exposed by removal of leaves or useless shoots to get the high colour so desirable, and the final thinning should not be deferred, as all fruits should now finish well. A good mulch of rich manure will assist in finishing up the crop, but if delayed the fruits reap little benefit and a late growth results, which does not ripen well. Remove any useless laterals that are not required. Young trees should be allowed free extension of branches, as advised for mid-season trees, and crowding avoided.

**THE ORCHARD HOUSE.**—Much the same routine is necessary with trees in pots as advised for trees planted out, but more care is necessary in watering and securing firm sturdy growths for next season. Mulching must be regularly attended to, as the mulch frequently gets washed away with repeated waterings. A good mulch at this season is horse droppings that have slightly heated, with a liberal dressing of bone meal or other good fertiliser given on the surface before the mulch is applied. The waterings, so necessary for pot trees, will soon absorb the food from the manure, and by keeping the surface cool plenty of top roots will be made. In addition to the food advised, it is well to water frequently with liquid manure, and if a bag of soot can be immersed it is of great help in keeping the trees in a vigorous state. The syringe must not be spared, with ample supplies of air. Pinching and regulating the wood will still be important, as the trees laden with fruit have a great demand upon them, so that it is well to remove wood not required. Trees that have borne a crop and are well furnished with clean healthy wood may be removed into the open, plunging well over the rims of the pots, damping overhead daily when the sun leaves the trees, with ample supplies of moisture. Cherries and other early fruits are much benefited by removal if due attention is paid to the roots, and in the case of Peaches or Nectarines, give abundance of air to these trees as the fruits mature. Trees in the open grown this season specially for house culture next year will well repay liberal treatment to get strong well-ripened wood, stopping the shoots except extensions at the sixth leaf and pinching any lateral growth hard back. Feed freely and mulch over the surface. Now is a good

time to remove Pears, especially the early varieties, to warm sunny borders, taking care the roots are not exposed to the rays of the sun. The same remarks apply to Plums, except the late varieties, which should be kept under glass. A general overhauling of trees in this house will be beneficial, as many will now require cooler treatment and benefit by open-air exposure. Peaches and Nectarines where repotting is required may be prepared for the same by free exposure, and when the new wood is well matured a shift may be given into larger pots, but it is well to keep the trees under cover till the new roots reach the sides of the pots, when they may be removed into a south or west border, plunged, and the surface soil covered with a mulch of straw litter, the trees being syringed daily and watered carefully till the pots are full of roots. In potting use a good calcareous loam, old lime rubble (a liberal proportion of bone-meal if a large shift is not given) and ample drainage. Trees not requiring a shift should be liberally fed after the crop is cleared, and if the wood is matured they may be placed in the open and syringed daily in the evening.

G. WYTHES.

#### TABLE DECORATIONS.

Will some reader of THE GARDEN kindly give a few hints as to table decoration? I should be glad to know how to arrange flowers and Ferns on a dinner table.—F. THOMAS.

\* \* \* "F. T." having adopted this term rather than the far wider one of "arrangement of cut flowers," the remarks that follow will bear more particularly in the direction of the former heading. It is a very wide subject upon which to treat, for what prevails in one establishment may not in another. Both the selection of material and the choice of vases will vary greatly. A decided improvement has been manifested in table decorations during the past few years. There are some of whom it must be stated that they will apparently never learn what lines to follow. There is plenty of opportunities at the present day both for taking notes and for impressing upon the mind the most tasteful styles of arrangement. For this we are greatly indebted to the encouragement given by the most noteworthy of the horticultural societies at their shows. At these exhibitions there are nearly always sufficient examples of tasteful arrangements as well as of those quite the reverse, so that comparisons can easily be made. Many very beautiful designs are to be seen in the shops of the best florists who make cut flowers a speciality, but these have more particular reference to other than table decorations.

#### FLOWERS AND FERNS.

I note that "F. T." makes use of these words; a few comments thereon may not therefore be out of place. At one time—and that not so very many years back—it was thought quite the correct thing to use Fern fronds (more particularly those of the Maiden-hair) with flowers, be the latter what they may. This custom has been broken through, I am glad to say. I have not the least objection to this beautiful Fern, but its use with all kinds of flowers is quite out of place. In the similar way that rich food will cloy the palate, so will Maiden-hair Fern the sight if it be used indiscriminately. No one of taste would now think of letting the Maiden-hair entirely supplant the foliage of the Rose when Roses are being used. A frond or two here and there would aid in the effect, but let the foliage of the Rose predominate. This may be accepted as a general rule—wherever possible rely upon the foliage of the plant to accompany its flowers. For instance, I will quote the Daffodils; with these

use their own foliage most decidedly; the Lily of the Valley and its own leaves; the Water Lily and its foliage, or some other resembling it; the Gardenia and its own sprigs, with several leaves upon them, cannot be surpassed; the Tulip, with its own leaves; the Roman Hyacinth, of which the most suitable leaves are those fully developed, the spikes being often cut whilst the foliage is still too short; with the Eucharis either use small leaves of the plant itself, or such as those of the green-leaved Aspidistra; with the Camellia, its own foliage most decidedly (what can surpass it?); the Tuberosa in vases looks best with its own or similar foliage; if Chinese Primulas are being used, let their own leaves be used also here and there. But some may say, "What about Orchids? Is it advisable to use their own leaves?" No, most decidedly not, but there are other kinds of foliage which may be used. From the stove there are the leaves of Caladium argyrites and other kinds; those of Fittonia argyrea (shoots rather than leaves); Cyrtodeira metallica, the shoots of which look very beautiful with light-coloured Orchids; Panicum variegatum, of which long sprays are the best; Asparagus plumosus, either as plumose sprays or long trailing shoots; Myrsiphyllum asparagoides as sprays also (a cooler house will suit this); Cissus discolor in sprays, fairly well matured, beautiful with Cattleyas. From out of doors can be taken the shoots of such hardy plants as Acer palmatum, whilst growths of the hardy Panicums may be quoted as examples amongst Grasses. From amongst Ferns themselves there is a wide field of choice. Take, for instance, the Davallias, which are of most diverse character, nearly every one lasting exceedingly well in a cut state, several of the Aspleniums, the Nephrolepis, the larger Adiantums, the Pterises, and the Gymnogrammas—all of these will serve a good purpose. Omission should not be made of the Rex type of Begonias, nor of such species as B. metallica. Although these instances have been quoted with more particular reference to Orchids, they are quite as applicable to other flowers when "suitable."

#### SUITABILITY OF FOLIAGE TO FLOWERS.

Some idea of this may be gathered from what has already been written; there is, however, a kind of affinity distinguishable in many instances. Lilies and Grasses associate well together. Take as a case in point two varieties of Lilium lancifolium, or one only for aught it matters, and as additional foliage use the shoots of Eulalia japonica or Elymus glaucifolius. A centre-piece arranged with these alone and a trailer around the stem, with a few more shoots springing from its base, amongst which might nestle a few flowers of Eucharis or of Pancratium, a few bolder leaves resting upon the cloth as a finish. Supposing it to be the spring season with the Spanish Squills in flower (Scilla campanulata), with one or more colours of these a few shoots of the common Ribbon Grass would look well amongst the spikes. The bronzy foliage or shoots of some of the Tea Roses cannot be surpassed with the yellow and other soft shades of colour to be found in their own particular section. To enumerate further under this head is scarcely necessary; many other examples will suggest themselves at various seasons of the year. Again, there is the Chrysanthemum, for which scarcely anything more suitable could be chosen outside of its own genus than the shoots of Mahonia aquifolia. If the flowers of the Chrysanthemum be either yellow, or in its shades merging into bronze, or white, or any other light colour,

take the bronzy-tinted shoots; if the colours be brighter, then use the green shoots.

#### ARRANGEMENT OF THE FLOWERS.

Under this heading I shall at once condemn the evil of overcrowding; it still prevails, but not to the same extent as it used to do. One most fertile source of overcrowding arises from the use of flowers with too short stems. This is a common mistake made when cutting them, caused often perhaps by the gatherer not being the arranger. It may be said against long stems that it is often a waste to cut such, but if half as many in quantity will suffice with long stems (which they will in many instances), where does the waste come in? It is rather the reverse than otherwise. In the arrangement itself always endeavour to secure a light and graceful effect. If the thought should arise that too many flowers have been used, reduce the quantity and test the result of doing so. In most instances a groundwork of foliage is needed to start with. This is more essential if it be a stand with a broad base resting upon the cloth, upon which some of the flowers must of a necessity repose. An epergne with a tall stem requires first to be furnished with drooping foliage, and flowers too, if they are to stand. Afterwards add both foliage and flowers in unison, not all the flowers first, or *vice versa*, otherwise the proper balance of one to the other cannot be attained. I have often seen the flowers crowded together first, touching one another in fact; then to remedy this some Maiden-hair Fern fronds or Grasses or lighter flowers would be added to *lighten* the appearance, which if arranged in a more natural manner would never be too heavy. This process of lightening is absurdity itself.

#### FORMALITY IN ARRANGEMENTS

is another and a frequent mistake. The assumption that each particular flower of any given kind (be it what it may) must each have the same length of stem or be used at set distances apart, as if mathematical precision was the prime object, should not for one moment obtain; if this be countenanced there is an end to the tasteful disposal of flowers at once, and it is merely a matter of detail. To first use all the flowers with short stems and then dot others over them in a methodical fashion is also wrong; the reverse mode of procedure is infinitely better, but a combination of the two is the best plan to adopt. In making a bouquet of the all-round shape, the centre is the starting point. Let the same method be followed in arranging either tall vases or cornucopias or bases resting upon the cloth, and a better result will be secured. It is often otherwise, however, the starting point being the outer edge, with possibly just so many flowers of this and the same of that, these probably being inserted alternately.

#### THE MIXTURE OF COLOURS

is the point where many fail; in this respect it is very easy indeed to make a mistake. By all means avoid violent contrasts; scarlet and white, red and yellow, are sufficient to illustrate this. The judicious combinations of shades of one particular colour, such as the yellows, in which there is a great variety, one blending harmoniously with another, must be studied. The same occurs in the pinks as they merge into the rosy or red shades. With white flowers it is better to use soft colours rather than brilliant ones. The conditions under which a table is being decorated must also be studied; the colour of other things besides flowers has to be considered; so also

has the light. On the whole, the less use that is made of mixtures the better will be the result. One colour should prevail above others also, for if two colours in about equal quantities be used there is a want of decisive effect. Two or more shades of one colour, and of one particular flower, taking the Rose as a case in point or the Sweet Pea, are most commendable; this tends towards simplicity, which is always desirable. Between some flowers and others there is a close affinity, although not of the same family; thus stellate or star-shaped flowers blend well together. On the other hand, double and single flowers should be avoided in mixtures as far as possible. Roses with Marguerites is given as an instance of this incongruity. Single Roses look charming with Water Lilies, and so do Forget-me-nots.

#### THE SELECTION OF VASES

is not in every case that of the best, but it will be a difficult case indeed if the arrangements cannot be adapted to the circumstances. Vases which obstruct the view at the line of sight are not desirable; those with a proportionately broad base and a slender stem are easy to arrange, so as to avoid this defect. Slender stems with heavy tops should be of sufficient height to prevent any obstruction of the view. Nothing amongst colours in glass is better, or even equal to, the plain or natural colour, whilst ornamental vases, which are as ornaments sufficient of themselves, have to be arranged very judiciously, otherwise their beauty will be hidden. Where possible such vases as these are better adapted to plants than to cut flowers. Uniformity in either height or size is most undesirable; the centre-piece should be larger in every sense than the rest and its view should not be intercepted by the others. In exhibitions one often sees classes for three stands "suitable for dinner-table decorations." These—as almost invariably shown—are too nearly of one size; hence, if put upon a table with all other accessories, it can at once be seen that the outer ones are too large. It is only by experience in the actual work upon a table that a correct idea of size can be had. Too many vases are an encumbrance rather than otherwise; this will not tend to a good effect, nor will the use of a large number of smaller ones in preference to a less number of larger size. Some of the fully-laid floral decorations (only) as shown, which, of course, consist of more than three stands, are simple absurdities, no room being left for plates, dessert, or other necessary adjuncts to a properly laid-out table. Those who arrange such as these know but little of the practical detail, whilst those who place them in the prize list in preference to workable designs are equally as ignorant. Coloured drapery or cloths are the prevailing idea with some, but, personally speaking, after an experience of these, I should much prefer to do without them. Far better to depend upon the flowers for colour effect; they cannot be equalled, much less surpassed by anything artificial. Trailing sprays of such climbers as *Asparagus plumosus nanus*, *Myrsiphyllum asparagoides*, Veitch's *Ampelopsis* or *Lygodium scandens* are infinitely better than millinery embellishments. Even where they are used there is a difficulty at times to select the flowers that will harmonise with them. I had once to contend with this. One central cloth was red and another was green; between the two there was not unfrequently a difficulty. Where sprays of such climbers as those just named, or any other that may suggest itself, are used it is always possible to add a few flowers, but be moderate in their use. In every case endeavour as far as possible to use flowers in a

natural manner. We do not want to see such incongruities as *Lapageria* blooms, which after mis-spent time has been bestowed upon by wiring, standing erect, nor do *Cattleya* flowers look well with the lip upwards instead of down, nor should blooms of the Water Lily be elevated; let the last always be kept low. In the use of Orchids it is always possible to mix both diverse varieties of form and colour in the same arrangement; they have peculiar charms and harmonies not possessed by other flowers. —J. HUDSON.

## ORCHARD AND FRUIT GARDEN.

#### EARLY PEACHES.

WHEN I grew the Amsden June, Alexander and Waterloo Peaches side by side on the open wall, the Amsden June never grew so large, neither did it crop so well as the other two. Certainly the colour was darker and the flesh probably a trifle sweeter. I thought it a valuable early Peach and well deserving of wall space, but it was useless to grow the three, so I dispensed with it, giving preference to the Waterloo and Alexander. Waterloo is my favourite, as it has so far always produced an abundant crop of fine fruit both inside and outside, and if gathered at the right time and treated with some amount of caution just before ripening the flavour is very good indeed, in fact better than in some of the larger mid-season varieties. Cultivation has a great deal to do with the quality; especially is it so with these American kinds. Overcropping and too close and moist a temperature just when the fruits are ripening are two of the greatest evils. Waterloo with me under glass usually grows to a good size. Though the fruits have a great resemblance to those of Alexander, there is a wide difference in the leaf, and those who have any doubt respecting the two should examine the leaves, when the matter may very easily be settled. In the Waterloo we have very large, deeply-cut, kidney-shaped glands, usually from two to five on a leaf, quite as large, if not larger, than those of Lord Napier Nectarine. In Alexander the glands are quite the reverse, being small, some round and others cut and kidney shaped, two to four on a leaf being the rule. I have always found Waterloo the largest here, although the size varies according to the stock on which the trees are worked and the soil in which they are planted. I think sometimes a black mark is given these American Peaches when it is not altogether the Peach, but the cultivation, as frequently we meet with trees planted amongst much later kinds, and to suit the latter the former do not get air enough at the time of ripening. The fruits should always be carefully gathered a day or two before being ripe and placed on some soft material in a cool airy room to ripen up. They will not keep for any length of time, but quickly become like Williams' Pear. I should not for a moment hesitate to plant Waterloo and Hale's Early side by side for supplying ripe fruits by the middle of May. No hard forcing would be required if the trees were started by the end of January.

I was glad to read "J. C.'s" favourable remarks respecting Early York. I never knew it to fail on the open walls, and it is truly a delicious early Peach; it always grew well under glass. Hale's Early when well grown is a first-rate kind both for indoors and out, but requires great care in gathering, as the fruits frequently

clasp the shoots so tightly that much damage is done when taking them from the trees.

H. MARKHAM.

*Mercworth Castle, Maidstone.*

### MELONS.

THE season so far has been all the Melon grower could wish, and the abundance of sun will have given the fruit a rich flavour. No matter how much sun heat is obtained, without special care in the way of watering, airing, and finishing the fruits, there will be poor flavour. The fruit illustrated (Albert Victor) is a type now much grown, being of medium size, roundish, and well netted. These medium-sized fruits are much superior to large, coarse ones, some of which sadly lack flavour, the most important point in the Melon. Albert Victor can be recommended for its good qualities, free growth, and nice appearance, three important points the Melon grower must consider. I think there is less trouble with the newer varieties of Melons in the way of setting, as now most varieties set so freely there is no trouble in obtaining heavy crops. Of course, much depends upon culture. All have not the same convenience to grow the fruits, and in mixed houses there is a difficulty, as moisture at certain periods of growth is not conducive to free setting. If there is a fault, it is that some of the newer kinds grow so strongly, and do not then set so freely if given rich food or large quantities of manures as heating materials. Few fruits are raised so readily as the Melon, and few fruits deteriorate so quickly, as if several varieties are grown in one house they become so much mixed that they lose their good qualities and are flavourless. Melons cut before they are ripe rarely have the rich aroma so desirable, and fruits from plants that have been prematurely dried off cannot be depended upon for flavour. Many growers plant much too close, and by crowding do not give the plants a fair chance, as if a large grower is cramped in a small space it is impossible for it to fruit freely or set well, the crowded growths preventing the plants setting, the results being canker and insect pests. The best crop of Melons I ever saw was in a long, deep-pitched house, six plants of a new variety being grown in a space usually devoted to twenty-four, and the results were most gratifying, as there was no disease, and the plants, grown on the extension principle, were so readily managed, there was a great saving of labour and no difficulty in obtaining a second crop, the plants being clean and vigorous. Properly treated, the plants will cover a considerable roof space, and if not over-cropped at the outset, will produce three crops when top-dressed and kept clean. Keeping the plants clean in crowded, over-cropped and restricted areas is the most difficult part of culture; whereas with ample space there is greater freedom from insects, the syringe can be used to better advantage, and the work of stopping, setting and training is not nearly so troublesome. I have in these pages described a very different mode of culture to the one now advised—namely, by cordon plants, but that was for a special purpose for a catch crop; and with a deficiency of soil and root space the result was all one could desire. As the fruits were required large (being for sale), flavour was the last point considered, large quantities of liquid manure being given from the setting period. Growing Melons in a restricted space is doubtless the cause of many failures, cracking being one of the worst. Want of food and moisture

is the forerunner of black fly and red spider, and to get good results generous treatment should be given, as for Cucumbers. Melons require a stronger soil and less food at the start, but I am sure many plants are starved too much in their early stages, and better results could be secured by growing on the extension principle, cutting the fruits directly they commence to crack at the stalk.

G. WYTHES.

**The Plum aphid.**—Up to this date (June 17) Plums have been wonderfully free from insect foes, but I see they are beginning to become infested slightly with the above aphid. As this pest increases at an enormous rate and will quickly spread over all the trees unless prevented, no time should be lost in destroying this enemy immediately it is detected. Any proved insecticide applied warm will effectually settle this foe and stop its doing further mischief.—W. G. C.

**Two good Cherries for an unheated house.**—When at Mairdiffe Court, near Aberga-

*Melon Albert Victor. From a photograph sent by Mr. Ernest E. Peacock, Bewdley Villa, Bath.*

venny, recently, I was pleased to see in an unheated wall case two well-known Cherries bearing splendid crops of large, well-coloured fruit, viz., Black Tartarian and Governor Wood. Other varieties were bearing good crops, but the two named surpassed all others in every respect, and Mr. J. Newell, who now has charge of these gardens, speaks in the highest praise of their merits for planting in the glass wall cases or in unheated houses, as they rarely fail to produce heavy crops of fruit.—G. C.

**Syringing Vines.**—Unless great care is taken red spider will be much in evidence this season, especially on light soils and also perhaps where the root action is not very good. Dryness at the root and a hot and close atmosphere will soon bring red spider in shoals. Even in the best managed vineries a sharp look-out has to be undertaken. A system which I have practised ever since I had vineries under my sole charge is, during these hot and dry periods, to give the Vine leaves a good shower bath in the evening just as the sun has gone off the roof. Of course, only perfectly clear soft water must be used, and which must only be directed at the foliage, keeping the water as clear of the bunches as possible. A

careful man will soon manage this work and with no harm to the Grapes. An extra force must be put into any dry or hot corners, as here the spider generally gains a foothold and quickly works destruction. If carefully undertaken, these washings will prove most refreshing to the Vines.—A. YOUNG.

### MUSCAT OF ALEXANDRIA GRAPE.

JUDGING from my own experience and visits to other gardens during the past few weeks, this magnificent variety has set unusually well this year, and with a remarkable absence of stoneless berries. Every year I crop all the Vines heavily that are under my charge, and the remark is frequently made, "You may go on all right with most sorts, but some day you will come to grief by cropping your Muscats in that style." So far such has not been the case, nor do I think it will occur from that cause, for with ample drainage I know of no variety of Grape that will enjoy an ample supply of plant food more gratefully. At the same time I would not suggest the

use of any one particular manure, no matter how good and reliable it may have proved, for Vines can be surfeited with good fare if confined to one particular diet. Again, in the feeding of Vines there is a right and a wrong way of performing it. Of this I have seen several instances during the past few years in which the rainfall has been below the average. Many of us are too much guided by custom in watering Vines, not making sufficient allowance for the want of water in the subsoil, and for the greater evaporation continually going on in a hot, dry season like the present one; consequently the borders are much drier than one imagines, or as indicated by the surface. Supposing the border to be dry, and it is thoroughly saturated with liquid manure, or perhaps a powerful chemical fertiliser, the result is frequently disastrous, and, I believe, is a prime cause of shanking, mildew, and other evils. In the first place the roots are languishing more for moisture than for stimulants. Some varieties of Grapes will endure such treatment without any apparent ill-effects, but not so Muscat of Alexandria. I have seen the berries commence to shrivel before they were ripe, and shank-

ing suddenly set in from this injudicious application of fertilisers, but perhaps the worst instance I ever saw came before me last year. A friend, who had none too good a water supply, had a house of Muscats just commencing to colour, and, as the border had become very dry, he gave it a thorough soaking, also using diluted liquid manure, with a fairly strong dressing of chemical manure on the border. Instead of giving an extra push to the Vines, as intended, the bunches commenced to rot in a wholesale manner. If the border of the vinery is drier than it should be, it is much better to give it clear water at first, especially if planted with Muscats, and then in a few days supply something stronger; by this means no harm will be done, but much good, as the roots will be in a condition favourable for taking up the fare provided for them. In a season of drought such as we are now experiencing it is better to err on the side of too much water than too little. Of course, no hard and fast rules can be laid down as to how often Vines should be watered to keep them in a healthy, vigorous state, as soils, drainage, &c., exercise a great influence. In some cases where the soil is light and the border shallow it may be

necessary to water once a week, even when there is a good mulch of manure on, and on heavier soil, with possibly deeper borders, no watering may be needed for three weeks or a month.

As Muscats that were started in February or early in March will soon be commencing to colour, it may be stated that there should be no hurry in tying back the leaves to permit the sun to have free access to the bunches. Personally, I do not believe in the system of fixing back the foliage, for if the laterals have been kept in proper order and the growth or leaves not overcrowded, sufficient light will be admitted to give the beautiful amber colour so much prized without the risk of rusted berries, which are a great disfigurement if required for exhibition, though frequently no detriment for home consumption. Another cause of injury to Muscats is the sudden reduction of moisture in the atmosphere and the lowering of the temperature by giving front ventilation as well as at the top of the house day and night when the berries commence to colour. It would be interesting to know how much the early shrivelling of the berries could be attributed to those two influences. Over-cropping is undoubtedly a great factor in the premature shrivelling of Muscats, but I think this greatly reduced atmospheric moisture and considerable fall in the temperature are more to blame than is usually admitted. The evaporation is equally as rapid while the Grapes are colouring, and if the foliage cannot obtain sufficient moisture for the proper performance of its functions, the fruit suffers to some extent. Take the ventilation again. If the temperature has been kept up to that required by Muscats until the time for colouring, and then it is dropped 10° or 15° day and night, with possibly a draught, it stands to reason that something will suffer; yet this is done in many places. By all means admit air to the Vines, but at the same time maintain a night temperature of at least 65°, with a rise of 10° by day. Of late we have had very cold nights, the thermometer on several occasions going below freezing point. This morning (June 17) ours was down to 32°, which means that with a little top and front ventilation on the vineries a fairly good heat must be maintained in the hot-water pipes to keep up the requisite temperature. Some employers think their gardeners ought not to require fuel for the houses during the summer, but this is false economy, as it not only severely handicaps a gardener, but, owing to the fruit not being so well coloured and highly finished, it is neither so well flavoured for home use nor so valuable for market. No Grape is more delicious than well-ripened Muscat of Alexandria, and reflects the highest credit on both the employer and his or her gardener. Again, for market perfectly finished examples will command a price above all other Grapes; therefore, ladies and gentlemen possessing vineries should not grudge the necessary fuel to properly finish the crops therein, as it is certainly to their interest to supply the same.

W. G. C.

**Strawberries for forcing.**—In a short note on the value of Noble for May supplies I fear I did not make my meaning quite clear, as "S. W. F." (p. 409) advises me to try Royal Sovereign. I purchased 100 plants of the new variety the day it was first exhibited, as I saw at a glance its good qualities, and though the cost was serious at the time named, I have had no reason to repent my bargain. During the week ending June 15 I gathered so many grand fruits and of such good quality, that it has repaid handsomely for the outlay two years ago. Last season the plants promised such a heavy crop, that I removed the flowers from one half of the plants, getting a fine crop of early runners. These this season have been forced, and a portion was planted last August for early fruits, and the yield was enormous. Altogether I have given it a comprehensive trial. So far I have not found it quite so early as Noble, but it is more prolific and superior in every way. A few days at the end of May or the early part of June are of great importance to growers, and I shall still plant Noble on a

warm raised border for early dishes. I do not think any single variety has paid better than Noble in the past, but doubtless it is now superseded by the one "S. W. F." advises. In my note as to its returns, I intended to prove that it had paid grandly. Market growers, too, have assured me that Noble was their sheet anchor if specially grown, that is as yearling plants on rich land and in the most favourable position. It is strange how the variety advised varies in certain soils. If I am not mistaken, "S. W. F." lives in a favoured southern locality, where the land is noted for its rich crops of fruit. My soil is very bad for Strawberries, being shallow and on gravel, anything but good Strawberry land. Noble from yearling plants only cropped once is our earliest fruit. Royal Sovereign is six days later, but freer, and will, I hope, be equal to Noble for hardness in severe winters when we lose many of the Queen and Pine family. The most robust grower is Noble, but the Royal Sovereign is very free, bears enormous crops, is far ahead of older kinds, and will become a greater favourite on account of its having withstood the drought admirably.—W.

**Dry weather Strawberries.**—Many growers have poor soils, a small supply of water, and limited means to apply the same, and if they can grow robust varieties, there is considerable gain and less anxiety as to the crop. The season of 1893 taught us a lesson as to the value of young plants compared with old exhausted ones which soon fail in dry seasons, bear small fruits, and require much water or food to keep them alive. There is an immense gain by planting annually and giving new quarters, well prepared, as the plants in specially cultivated soil give a much better return and can be depended upon. There are a few varieties specially good in dry weather, but Royal Sovereign tops the list. The fruits this season are grand and in quantity, and young plants have done remarkably well. Another good dry weather kind is Sir C. Napier. This grows well in most soils and is not so readily affected by drought. The small, but richly flavoured Vicomtesse H. do Thury is an excellent dry weather Strawberry. It succeeds where others fail, is a great cropper, very early, and one of the best for preserving. Laxton's Latest of All is a splendid hardy variety, doing well in seasons of drought; indeed, with me it is the best late variety, and gave very fine crops in 1893 when others failed. Oxonian also thrives well; this is also known under the name of Eleanor. The same remarks apply to Kitley's Goliath, a strong grower, its chief merit being its long-bearing qualities. Doubtless there are many others; for instance, Aberdeen Favourite is good, but these named have been given a good trial, and I note their value on light land.—G. WYTHES.

**Good packing Strawberries.**—Flavour and size in Strawberries are important points, but it often happens we want a fruit that will travel well. Noble, though one of the most profitable Strawberries grown, is a bad traveller, and unless carefully packed does not look well at the end of a long journey. The new Royal Sovereign is a good traveller, as after a journey of many miles it arrives sound and without blemish. Much always depends upon the packing, as the best Strawberries when only sent a few miles present a sorry spectacle badly packed, whereas well packed fruit in small punnets quite firmly wedged together and with little top space will travel well hundreds of miles, or the fruit may be packed in layers in shallow boxes, and at a journey's end be perfect if such material as soft leaves is used, wadding being most objectionable. Many of the Pine class pack grandly, having their fruits well protected with seeds. Keens' Seedling and other dark red glossy kinds require most careful packing. Laxton's Latest of All is a splendid fruit for sending long journeys. Some Strawberries are much more juicy than others, and will not bear packing when sent long distances. President and Sir C. Napier held their own for many years on account of their good packing qualities, but some of Mr. Laxton's seedlings, of which Royal

Sovereign is one of the very best, will doubtless out many old favourites. As to the best way to pack I will not now enlarge upon, as various methods are employed. The object of this note is to point out those that have firm fruits and are suitable for sending long distances. All the varieties mentioned are also noted for their good cropping qualities.—W.

#### BLISTER ON VINE LEAVES.

WITH your permission I will make two remarks on the carefully written article on this vexed question over the well-known signature of "W. I." (p. 410). The one refers to a matter of omission, the other of commission. From first to last the writer treats the matter as one of surface treatment or ventilation, and no doubt this is often the cause of it, but at times the cause of this leaf blister lies deeper down in the roots.

Then "W. I.," in his most careful and sound advice on early ventilation, says, "a little heat in the hot-water pipes is most desirable." The sentence is carefully worded. I duly note that "W. I." writes "a little heat," but then this caution is lost when he says that this little heat in the pipes in the early morning is most desirable. What for? The writer is advocating early ventilation, that fresh air should be admitted ahead of any advance of the internal temperature of vineries through the growing power or force of the rising sun. To accomplish this task—which is more difficult in practice than it appears on paper—the less heat in the hot-water pipes in the early morning the better.

Hence—especially through spells of bright weather—I have educated my stokers into having vinery fires very low, or quite out, and the pipes cold in the morning. Should the state of the weather (or of the crops) require it, the fires are easily lit and a little or much heat sent into the water pipes as required. Of course I had other reasons for practising this cool policy in regard to the artificial heating of vineries in the early morning. I have firmly believed that most of the checks, diseases, insects, such as spider, thrips, &c., that so often dash the hopes and blight the prospects of Grape growers, originate in this mixing to excess of fire and sun heat beyond the means provided by ordinary ventilation to properly regulate or skilfully control. Of course extraordinary means are still available, such as the opening wide of doors and the slipping down or off of roof lights. But no one knows better than "W. I." how dangerous these extreme means of keeping vineries cool are, and how fruitful of blister and other accidents or diseases they are likely to be. It is safer far to have the pipes cool or cold in the morning and start each new day with such artificial heat as the weather and crops are likely to require.

D. T. F.

#### PREPARING STRAWBERRIES FOR FORCING.

WITH so many new Strawberries the desire comes to give some a trial, but as these fruits vary so much under culture in different soils, it is well to try the new kinds in various ways to find out their value. A new variety hard forced may be very disappointing; whereas a few weeks later outside it may be the reverse. Another test, and one which is most satisfactory to all concerned, is to fruit a plant or two in the open, testing its qualities by the side of well-known forcing kinds. The grower cannot expect these plants which have borne fruit to give early runners also in time to fruit the following January or February. Plants for forcing require preparation to get the best results. My plan to get plants in quantity and as strong as possible is a simple one. I layer a certain number of plants for the purpose as early in July as possible, and it matters little how they are layered whether in small pots or turves. A piece of ground is well prepared, being double-dug, heavily manured, and got into condition for planting. The plants are turned out at the end of July, planted in hard-trodden land, watered

freely as required, and make a splendid growth by the end of September or early October. Being short of space, Lettuce is planted between the rows for an autumn crop. The distance between the rows is 2½ feet, the plants half that distance apart. These are the material for next season's forcing runners. The flower-trusses are kept picked off before they expand, and by the third week in May I have runners in quantity that will be fit to layer early in June. There are great advantages in this system; the plants are not spread over a wide surface, as a few rows of plants will produce a great quantity of runners. Plants grown specially for runners will give twenty times as many as those which have to support a crop of fruit. There is a great saving of time and labour, and much better plants are the result. Purchased plants for forcing cannot be depended upon. I have had them sent home in such a small state and so late that I now

firmness of its flesh and the thickness of its skin or other causes it also bears carriage well. It is a bold venture to pit the bearing properties of the Golden Spire against the Keswick Codlin or Lord Suffield at its best. But it is a marvellous bearer under favourable conditions of culture and treatment, the fruits forming themselves into trusses more than most varieties. Few varieties form better pyramids. Thinning alike of wood and fruit and feeding are essential to continuous cropping and the production of such high quality in Golden Spire or any other Apples as shall command the highest prices in our markets.—D. T. F.

#### COVERED WAYS OF HARDY FRUIT TREES.

THIS quite practicable way of growing fruit trees and shading walks is too seldom carried

counties may see how well fruit trees do in hard walks. It is not only in kitchen and fruit gardens that such a thing would be desirable, but even in flower gardens, if we could ever get out of the strait-laced notion of a flower garden which insists on everything being seen at one glance. There is not the least reason why a beautiful arbour of fruit trees would not be most effective and welcome in various kinds of flower gardens associated with hardy flowers, or otherwise. In some old English gardens there was a habit of "plashing" trees over walks—that is to say, growing trees like the Lime over walks, which naturally grew so vigorously that they had to be repressed with an equal vigour, and this led in the end to ugliness in the excessive mutilation of the trees, as may still be seen in some old gardens. One result of the

*Covered way of fruit trees. Engraved for THE GARDEN from a photograph sent by Mrs. Newman, Hazelhurst, Haslemere.*

always resort to home-grown plants for early forcing. It is a great loss to grow your plants and then fail. Much time is taken up in going over a wide area and getting the best runners from exhausted plants, and there is much time lost in watering during growth, so that getting the plants into a certain space where layering, watering, and other details can be carried out readily is a saving when labour is none too plentiful and early forcing essential. It should also be pointed out there is no waste in any way, as the plants after furnishing the runners will the following season give splendid fruit and in quantity. S. H. B.

**The Golden Spire Apple.**—"W. G. C." estimates this variety highly in stating (p. 410) that it is more profitable and reliable than Lord Suffield, Keswick Codlin or Lord Grosvenor. Even the novelty of its spiral form seems to help, not hinder, its sale, while its golden colour gives it a market advantage over such pale-faced varieties as Keswick Codlin and Lord Suffield. From the

out. Few things would give more satisfaction if the right sort of fruit trees were selected, and by the right sort we mean kinds of the highest excellence, which do well in their several districts. Although in gardens generally the shaded walk is not nearly so necessary as it is in Italy and Southern France, or even in the warmest parts of Germany, in a season such as the present shade is as welcome here as anywhere else, and as many of our garden designers in their wisdom have given us four times as many walks as anybody wanted, there is plenty of opportunity for covering some of them with fruit trees which, well chosen, would give us much beauty in spring, handsome fruit in autumn and lightly shaded walks. The very substance of which walks are made lends itself much more to the wants of fruit trees than the soft surface of the ordinary kitchen garden, so that by this kind of fruit culture we use, as it were, the walk itself and use it well. Anybody who notices the Apricot district of Oxfordshire and the neighbouring

frequent cutting down was a very vigorous summer growth of long shoots, which cast a dense shade and dripped in wet weather. Even Apple trees may be trained over walks, and will support themselves without wires or any structure, as we once saw a perfect covered way of them in a Sussex garden. We think the purpose of such walks would be equally well answered by training fruit trees over them, as they are trees which much more readily submit to such treatment and give the light and airy shade which is best in our country.

In choosing the kinds of hardy fruit trees for this purpose, the first place should be given to the best British Apples, which are as handsome in the early year as in the fall, and give the best fruit which our country can produce. The advantage of trellis-training is, that the shoots of the tree being fixed, they escape to a great extent injury from storms, which are so frequent in the autumn, and if we get a crop of fine fruit, it is more likely to come to maturity in this way. The very hardiest kinds of

Pear, Plum, and Cherry also would do well in this way, and small fruits might be easily grown to perfection. Moreover, if the very finest kinds of small fruit were grown in this way it would be possible to protect them easily. The trellis, whatever it was formed of, need not be confined to fruit trees only, but here and there wreaths of Clematis or other elegant climbers might vary the lines.

Mrs. Newman, who sent us the photograph of the covered way of Apples from which our engraving was made, says: "The trees are trained upon iron supports, and they bear a quantity of fruit. When in full flower, with a border of Pansies and Forget-me-not at their feet, and the distance of hill and valley beyond, they are a lovely sight." In this case, as we suggest, fruit trees have been used with excellent results in the flower garden or pleasure grounds. The photograph was taken in the garden of Mr. W. Jackson at Haslemere.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

JUNE 25.

THERE was a full and interesting meeting at the Drill Hall on Tuesday, not so large, perhaps, as the previous one. The Orchids were not so numerous as at the meeting a fortnight ago, but considering the hot weather and the difficulty of keeping flowers in perfection, there was a very fine display. The attendance also was good. Hardy flowers were a great feature, whilst fruit and vegetables were present in considerable quantity.

#### Orchid Committee.

First-first certificates were awarded to the following—

**DENDROBIUM ILLUSTRE.**—A hybrid between *Dendrobium chrysotoxum* and *D. Dalhousianum*. The plant partakes both in the growth and in the flower of both the parents. The sepals and petals are pale yellow, lip hairy, as in *Dalhousianum*, pale yellow in front, with a reddish brown disc. From Messrs. J. Veitch and Sons.

**LÆLIO-CATTLEYA C. G. ROEBLING.**—This, a hybrid raised from *Lælia purpurata alba* × *C. Gaskelliana*, is very distinct and beautiful; sepals and petals blush, lip deep crimson in the centre, beautifully margined with white. The throat is lemon-yellow, lined with crimson. This is a fine addition to the fine hybrids raised by Mr. Maynard at St. Albans. From Messrs. F. Sander and Co.

Awards of merit were adjudged to the following—

**LÆLIA GRANDIS TENEBROSA** (Charlesworth's variety).—An exceedingly dark form of the type and a good-shaped flower. From Mr. F. Hardy, Tarporley, Cheshire.

**LÆLIA GRANDIS TENEBROSA PITTIANA.**—A distinct form, in direct contrast to Charlesworth's var., having light yellowish sepals and petals and creamy white lip, lined with purple in the throat. From Mr. H. T. Pitt, Stamford Hill, N.

**CATTLEYA WARSCEWICZI VAR. LORD ROTHSCHILD.**—Differing from the type by having lost the characteristic white blotch in the throat, the dark colouring of the lip having absorbed the white. From Lord Rothschild, Tring Park.

**ORCHIS LATIFOLIA** (Glasnevin var.).—Differing from the type by its larger flowers and finer colour. From Mr. F. Moore, Glasnevin.

Botanical certificates were awarded to the following—

**DENDROBIUM INVERNUM.**—A small-growing and most distinct species, having flowers of the same size and as near as possible of the same colour as in *Lælia cinnabarina*. From Mr. J. Bradshaw, Southgate.

**PLEUROTHALLIS IMMERSA.**—A distinct and pretty species, with hairy, creamy white flowers. From Mr. R. I. Measures.

Messrs. J. Veitch and Sons had a very fine group consisting of many of their rare hybrids and other scarce species, amongst which were *Cattleya Schrederiana*, a natural hybrid between *Cattleya Walkeriana* and *C. superba*, L.-C. *Arnoldiana*, *Cattleya Gaskelliana alba*, *C. Mossie Wagneri*, L.-C. *Canhamiana alba*, *Epiphronitis Veitchei*, *Celogyne Dayana* carrying six fine spikes of flower, *Dendrobium glomeratum*, *D. illustre*, mentioned above, *D. Dearei*, *Miltonia vexillaria* in variety, two fine plants of *Disa Veitchei*, *Oncidium macranthum*, *O. phymatochilum*, *O. longipes*, *Odontoglossum hastilabium*, a fine variety, *O. crispum*, *Cypripedium Harrisianum superbum*, *C. Artemus*, *C. Curtisi*, a fine dark variety, *C. superbiens*, *C. orphanum*, *Cataseum tubulare*, *Thunia Veitcheiana*, a specially fine variety with deep rose sepals and petals and a fine dark lip, *Brassia verrucosa*, *Oncidium pulvinatum*, *Cattleya Warscewiczii*, *C. Mendeli*, *Epidendrum reniferum* and *Epidendrum vitellinum majus*. A silver Flora medal was awarded.

Mr. F. Hardy, Ashton-on-Mersey, Cheshire, was also awarded a silver Flora medal for a very fine and well-grown lot of plants, prominent among which were *Cattleya Mossie Hardyana*, a form of *C. Mossie Wagneri*, L.-C. *Arnoldiana superba*, L.-C. *Stella*, *L. grandis tenebrosa*, a fine plant carrying twenty-five fine dark flowers, *Sobralia macrantha alba*, *Sobralia Kienastiana*, *Cypripedium macrochilum* with three fine flowers, *C. Gowerianum superbum*, *Lælia grandis* (Charlesworth's var.) mentioned above, and some good forms of *Cattleya Mossie*.

Mr. H. T. Pitt, Stamford Hill, sent a pretty group, consisting principally of *L. grandis tenebrosa*, the variety *Pittiana* (noted above) standing out prominent amongst them. *Miltonia vexillaria rubella*, *M. Roezli*, a fine var., *Cypripedium Chamberlainianum*, some fine forms of *Odontoglossum crispum*, *Oncidium phymatochilum*, with a fine branching spike 5 feet long, and *Angraecum falcatum* were also included. A silver Banksian medal was awarded. J. Gurney Fowler, Glebelands, Woodford, sent some choice things, noteworthy among them being the *Walton Grange* var. of *Lælia grandis tenebrosa*, with its beautiful golden yellow sepals and petals and white blotch on the front of the lip; also a fine plant of L.-C. *Arnoldiana*, carrying two spikes with four flowers each; L.-C. *eximia*, with two flowers; and *Cypripedium Rothschildianum*. A silver Banksian medal was awarded. Messrs. Hugh Low and Co. were also awarded a silver Banksian medal for a small group, consisting of *Odontoglossum crispum* in variety, two plants of the new hybrid *Cypripedium Gertrude Hollington*, *C. Curtisi*, two plants carrying six flowers each, a fine *Cattleya Warscewiczii* with an extra large and intensely dark lip; *Celogyne pandurata*, with its distinct green petals and black lip; *Odontoglossum Lanceanum* and *Grammatophyllum Measuresianum* carrying a fine spike. Messrs. F. Sander and Co. had a small but choice group, amongst which were *Lælio-Cattleya C. G. Roebling*, described above, *Thunia Bensonae grandiflora*, *Cypripedium A. de Lairese*, a hybrid between *C. Curtisi* and *C. Rothschildianum*; *C. Dayano-Lowianum*, a hybrid in the way of *C. luridum*; *C. Kimballianum*, a supposed natural hybrid between *C. Rothschildianum* and *C. Dayanum*; *Cypripedium Massaianum*, the first hybrid raised in which *C. Rothschildianum* had been used as a parent; a very fine variety of *Cattleya Rex*, *C. Mossie* with a fine dark lip, *Cirrhopetalum picturatum*, *Lælia præstans*, and *Odontoglossum Galeottianum*. Mr. T. M. Burton sent *Cypripedium Burtoni*. The same cross had been shown by Mr. Hollington previously under the name of *C. Millmani*. Mr. T. Statter, Stand Hall, Manchester, sent a small group of rare and fine varieties, among which was the best form we have seen of *Lælio-Cattleya Canhamiana alba* with two flowers, L.-C. *eximia*, two fine varieties of *L. grandis tenebrosa*, *Cypripedium Rothschildianum*,

*C. Harrisianum superbum*, and *C. selligorum majus*. Mr. De B. Crawshay, Rosefield, Sevenoaks, sent *Lælia purpurata Venus*, a distinct and delicate form, and *Odontoglossum crispum Crawshayanum*, which had previously received an award of merit. Mr. A. J. Hollington, Forty Hill, Enfield, sent *Cypripedium Millmani* and *C. Aylngi*, one of the finest *Cypripediums* that has been raised, and a seedling *Cattleya* not named. Messrs. Charlesworth and Co., Heaton, Bradford, sent *Cattleya Mendeli* (Charlesworth's var.), in the way of *C. Mendeli Morganii*, but with larger flowers. W. Cutbush and Son, Highgate, sent *Odontoglossum crispum Niobe*, a well-shaped flower, with large brown blotch on lip. Mr. J. Foster Alcock sent *Gongora cassidea* bearing two fine spikes of flower.

#### Floral Committee.

First class certificates were granted to the following:—

**PHILADELPHUS BOULE D'ARGENT.**—This is one of a series of hybrids raised by M. Lemoine between *P. microphyllus* and *P. coronarius*. It resembles the former in habit of growth, being dwarf with erect shoots that are wreathed in flowers their entire length. The flowers are semi-double and intermediate in size between those of the two parents. Shown by Messrs. T. Cripps and Son, Tunbridge Wells.

**ECHINOCACTUS AUREUS.**—A most distinct variety of the Porcupine Cactus that will become popular now that more attention is being given to these plants. It is entirely covered with long spines, which are of a clear yellow colour. From Messrs. Sander and Co., St. Albans.

Awards of merit were granted to the following:—

**BEGONIA PRINCE ADOLPHUS OF TECK.**—A rich crimson self, the flower of medium size, with smooth flat petals. From Messrs. Laing and Sons.

**BEGONIA J. T. BENNETT-POE.**—This is of a light scarlet colour, with flat outer guard petals and a full centre. Also from Messrs. Laing and Sons.

**CALOCHORTUS VENUSTUS PICTUS.**—Another charming addition to this lovely family. The flowers are a little smaller than those of the type, but neatly shaped, of a purer white, with rosy spots at the base and the characteristic brown blotch on each petal. Shown by Messrs. R. Wallace and Co., Colechester.

**CARNATION COWSLIP.**—This has a fine flower of perfect shape, and is yellow, edged and flaked with bright rose. Shown by Mr. Martin Smith, Hayes.

**CARNATION LADY RIDLEY.**—A white self, with a full, well-formed flower, but it did not appear better than other white kinds. This also came from Mr. Martin Smith.

**CARNATION GEORGE CRUICKSHANK.**—This has a large flower, which is buff, flamed with scarlet, this latter colour predominating to the extent of making the flower appear almost self-coloured. Also from Mr. Martin Smith.

**CARNATION ZOE.**—A pretty variety of a most distinct shade of pink, practically a self, having only a few tiny dots of light purple on the petals. This also was from Mr. Martin Smith.

**LILIUM DALHOUSIANUM.**—This handsome hybrid Lily, whose parents were *L. dalmaticum* and *L. Hansonii*, is now well known, and a coloured plate of it was given in *THE GARDEN* of September 16, 1893, p. 260. A fine spike of it was shown by Mr. T. S. Ware, of Tottenham.

**PEONY MME. DE GALHAN.**—A charming herbaceous variety with a graceful loose flower, the outer petals rose-pink, shading to flesh, with a creamy white centre. From Messrs. Paul and Son, Cheshunt.

**TUFTED PANSY A. J. ROWBERKY.**—This is a fine addition to the rayless varieties and most valuable because of its deep rich yellow colour. It is the finest yellow self yet raised. Shown by Mr. G. McLeod, Chingford.

**POTENTILLA CALIFORNICA.**—Though by no means a new plant, it appeared as such to many who saw

and appreciated its beauty for the first time. A large bunch was shown, the flowers full, double, and very large, of a rich yellow colour, slightly tipped with red. Shown by Mr. M. Prichard, Christchurch.

**SWEET PEA CUPID.**—A miniature variety of which nine pots were shown, the shoots being about a foot long and profusely flowered, the flowers pure white and as large as those of the ordinary forms. We fail to see the value of this, which is a poor apology for a noble garden flower, and nothing will be gained by dwarfing Sweet Peas into comparative insignificance. The craze for a pigmy strain of our best garden flowers is to be deprecated. It was shown by Mr. Burpee, of Philadelphia.

The group of hardy flowers from Messrs. J. Veitch and Sons was most prominent, Delphiniums largely predominating, the spikes very finely grown and flowered. Some of the best were Agnes, light purple; Lord Balfour, purple and blue; Nahamah, deep blue; Lord Charles Beresford, light blue; Minerve, light blue and mauve-purple. Among species *D. nudicaule* was finely shown, also *D. eschmerianum* and *D. grandiflorum plenum*. Early Phloxes and Campanulas were also good. They also showed cut Roses in quantity, Teas and Hybrid Perpetuals making a fine display. A silver-gilt Flora medal was awarded. Mr. Ware's group of hardy plants filled much space, and his method of grouping each variety by itself is much to be preferred to the conventional way of indiscriminately mixing everything shown. In this group Lilies were well shown, especially *L. colchicum*, *L. pomponium*, *L. testaceum* and *L. Dalhousii*. *Brodiaea coccinea*, *Lychnis vespertina plena*, *Eryngiums*, *Delphiniums* and *Alströmarias* were all noteworthy. A silver Flora medal was awarded, and a similar award went to Mr. M. Prichard, of Christchurch, for a fine group of the best hardy flowers in season. *Delphinium belladonna*, *D. nudicaule*, English Irises, *Oenothera speciosa*, *Potentillas*, *Chrysanthemum maximum* M. Prichard, *Spiraea astilboides floribunda*, most profuse in flower, *Scabiosa caucasica* and *Orchis foliosa* were all well represented here. Messrs. Jackman and Sons showed hardy flowers in quantity, noteworthy being their *Delphiniums*, the scarlet Bee Balm, *Linaria dalmatica*, *Oenothera fruticosa* and *Iris Kampferi* in variety. Roses (both Teas and Hybrid Perpetuals) were also shown, and a silver Banksian medal was awarded. Messrs. Barr received a similar award for one of their characteristic groups, comprising many good things not shown elsewhere, as *Iris Monspur*, a noble, tall, late-flowering kind, of distinct and striking beauty. It is a garden hybrid between *I. Monnieri* and *I. spuria* and a plant that one should have a bold group of. A coloured plate of this was given in THE GARDEN of November 15, 1890, p. 462. *I. aurea*, *I. ochroleuca*, equally tall and handsome, were shown well; also *Eryngiums*, *Linarias* and the great *Senecio macrophyllus*. Messrs. R. Wallace and Co. showed *Calochorti* in larger quantity than they have ever done before, and the group was quite a centre of attraction. The varieties of *C. venustus* were most numerous on this occasion, and in addition to the kind that received the award of merit we noted *C. v. ocellatus*, a tall, robust form; *C. v. Vesta*, very handsome, with a large reflexed flower; *C. v. Vesta albus*, a perfect gem, creamy white, with sulphur base, free from any spot or blotch; *C. roseus*, a rose-tinted form, and the brilliant scarlet *C. Kennedyi*, which was figured in THE GARDEN February 11, 1893, p. 108. English Irises were well shown, also *Brodiaeas* in variety, including the curious climbing *B. volubilis*, and *Liliums*, the varieties of *L. elegans* being numerous in several most distinct and striking colours. A silver Banksian medal was awarded. Messrs. Cutbush and Sons received a similar award for a very fine group of Malmaison Carnations, the plants in pots carrying splendid flowers.

Roses and hardy flowers were shown by Messrs. Paul and Son, the Roses mostly free-flowering garden kinds, also new and old single varieties

such as Carmine Pillar, especially rich in colour; Reine Blanche, a lovely variety of cupped form and creamy white with rose tipped buds; R. Andersoni, deep clear rose colour, distinct and striking; R. macrantha, blush, shading to white with extra large flowers; R. moschata alba and others, all most desirable sorts that ought to be common in our gardens. A bronze Banksian medal was awarded. Messrs. Dobbie and Co. exhibited a fine group of show, fancy and tufted Pansies and Sweet Peas all grown at their new nursery in Kent. The Pansies were remarkable alike for their fine size and freshness in spite of the tropical sun that has daily shone upon them. The Sweet Peas were also good, all the best new and old varieties being shown. We made note of Orange Prince; Firefly, bright red; Mrs. Eckford, the nearest approach to yellow yet raised; Blanche Burpee, Emily Eckford, and the good old Princess Beatrie, not yet surpassed in its particular shade. A silver Banksian medal was awarded. Messrs. Cheal and Sons, of Crawley, received a bronze Banksian medal for tufted Pansies in quantity and hardy flowers.

Cactaceous plants were represented by two large groups, but only one was entered for the prizes offered, the first prize being awarded to Mr. W. C. Ludford, Fernlea, Four Oaks, Sutton Coldfield, Birmingham. Many kinds were shown, but hardly any in flower. Messrs. Cannell have evidently turned their attention to this class of plants, and they showed a very extensive group, to which a silver Flora medal was awarded. Other exhibits were *Pelargonium Henry Jacoby* in double form from Mr. Cannell, Philadelphia; *Lemoinei* from Mr. A. Waterer, a flowering branch of *Ficentia californica* from Mr. F. W. Moore, Glasnevin, new garden Roses from a variety of crosses from Lord Penzance, a buff-coloured self Carnation named Lady Penzance, and *Dipladenia atropurpurea* from Messrs. Sander and Sons. Mr. G. Farini showed double *Begonias* in a most ugly way, the blooms in tubes on the conventional green boards without a leaf or foil of any sort. Mr. W. Taylor, of Hampton, showed a new crimson Rose named Robin Lyth, and *Delphiniums* were shown by Mr. Mann, gardener to Mr. C. E. Thompson, Penhill, Cardiff. Messrs. Coops, of Tunbridge Wells, showed a quantity of *Hypericum Moserianum* tricolor and a variegated variety of *Daphniphyllum glaucescens*.

The prizes offered for hardy flowers did not bring out much competition. Mr. G. H. Sage, of Ham House, Petersham, was first for twelve bunches. He showed *Delphiniums*, Irises, Iceland Poppies, *Centaurea macrocephala*, *Paeonies*, *Campanula persicifolia*, *Lathyrus latifolius*, Lilies, *Oenothera Fraseri*, *Chrysanthemum maximum*, *Eryngiums* and *Potentillas*. For eight bunches, Mr. C. Herrin, The Gardens, Dropmore, was first, his exhibit containing good bunches of *Verbascum vernale*, *Clematis recta*, *Campanula persicifolia* and *Delphiniums*. Miss Debenham, St. Peter's, St. Albans, was second. For twelve spikes of *Delphiniums*, Mr. A. Crossman, gardener to Mr. J. Brutton, Yeovil, was first with a good exhibit of five spikes, the best varieties being Duke of Teck, Ultramarine, Agnes Kelway, Lorenzo and David. The same exhibitor was also first for twelve bunches of herbaceous *Paeonies*, this being the only lot forthcoming, as owing to the heat and drought they are mostly out of flower now in gardens.

#### Fruit Committee.

The work of this committee was heavier than usual, Melons being shown in quantity. Tomatoes were good and Strawberries equally numerous. Good collections of Pine-apples and vegetables were staged.

A first-class certificate was awarded to—

**STRAWBERRY MONARCH.**—A very fine wedge-shaped fruit, beautiful in colour and firm in flesh. It is a cross between Latest of All and Captain, and partakes of the British Queen flavour, but is more robust, a heavy cropper, and does well on

light soils. From Messrs. Laxton Brothers, Bedford.

Awards of merit were given to the following—

**MELON BISHOP'S FAVOURITE.**—A white-fleshed fruit, above medium size, slightly netted, and with a good depth of flesh, very sweet and well flavoured. This was sent by Mr. A. Bishop, Westley Hall Gardens, Bury St. Edmunds, Suffolk.

**PEA CARTER'S DAISY.**—This is one of the very best types of dwarf marrow Peas grown. It has large pods containing seven to nine Peas, is a heavy cropper, grows 18 inches in height, is an excellent dry weather variety, and valuable as a second early. Shown by Mr. G. Wythes, Syon House Gardens, Brentford.

A dozen very fine Queen Pines with scarcely any top were staged by Mr. Coomber, The Hendre Gardens, Monmouth, the fruits being well ripened, of bright colour, and very even all through. They were much admired, and a silver Banksian medal was awarded. Messrs. Fellows and Ryder, Orpington, Kent, staged a dozen plants of the new Duke of York Tomato laden with large fruits of first-class quality and fine colour. It is a most prolific kind, and certainly one of the best new kinds since the advent of Perfection. A silver Banksian medal was awarded. Messrs. Laxton Bros. showed fifty dishes of Strawberries, including most of their new varieties, Leader and Monarch being specially fine. Royal Sovereign was also good. The dishes of Competitor, Commander, Waterloo, and Latest of All were noteworthy, and mention must be made of Unser Fritz, Admiral Dundas, Auguste Nicaise, Scarlet Queen, Kimberley, and some of the Pine section.

From the society's garden, Chiswick, Mr. Barron staged trusses of growing fruits (about a dozen), including some varieties rarely seen. Among them we noted Princess Royal, Leader, Glengary, Bothwell Bank, Dr. Vaillard, Acquisition, Souvenir de Bessent and Dr. Morere. Mr. R. Gilbert, Burghley Gardens, Stamford, showed some remarkable fruits of Royal Sovereign of high quality, the flavour being all one could desire. A cultural award was deservedly given. Mr. Collis, Bollo Lane, Chiswick, staged May Queen Strawberry in nice condition. Messrs. Cannell and Sons, Swanley, sent very good Royal Sovereign; and Messrs. Rivers, Sawbridgeworth, sent nice dishes of the Early Rivers Nectarine, from pot trees grown in an intermediate house. Rarely have so many Melons been staged, and, considering the favourable season, none were remarkable for high flavour; many were good, but not superior to existing varieties. Mr. G. Norman, Hatfield House Gardens, Herts, showed large, bright fruits of Hatfield Scarlet, somewhat like Blenheim Orange, deep flesh and well netted. A cultural commendation was given. Mr. Mortimer, Rowledge Nursery, Farnham, received a cultural commendation for twenty-four very finely-netted, medium-sized fruits of Eclipse, a variety which received an award of merit last season. From Mr. O. Thomas, Royal Gardens, Frogmore, came the Duchess, a new white-fleshed kind, but over-ripe. Mr. G. Wythes, Syon House, Brentford, sent two seedlings—Champion, a fine fruit not quite ripe, and the Gem, a small pale green variety. Mr. Bishop also sent other seedlings in addition to that certificated. Mr. Brooks, Red Rue, Andover, Mr. Johnson, Duffield House Gardens, Stoke Pogis, Mr. Ashton, Glossop Hall Gardens, Derby, Mr. Ward, Longford Castle Gardens, Salisbury, also sent seedling Melons; the last-named sent one named the Earl, which was given an award late last year.

Vegetables occupied considerable space. Messrs. Veitch, of Chelsea, sent a very fine collection of Cabbages and Peas. The Cabbages had good compact heads, the best being Ellam's Dwarf, Nonpareil Improved, Little Pixie, very nice for table; Veitch's Maincrop, a market form, and very large; Early Offenham, a conical variety. Earliest of All, Veitch's Matchless, Early Dwarf, York, very compact habit; Early Market, Enfield Market, Large York, a loose kind, an

Hardy Green Curled. Peas in eighteen varieties were shown with dates of sowing and gathering, the earliest varieties being Exonian, Veitch's Early Marrow, Laxton's Alpha, Dr. Hogg, and Chelsea Gem, these being fit the middle of June from outside sowing; Wm. Hurst, Gradus, Excelsior, and William I. were also good. Mr. Wythes also showed Peas, the varieties being Stratagem, very fine; Webb's Senator, a new variety with a full pod, much curled; and Daisy, already described; also a very nice lot of Veitch's Early Foreing Cauliflower, with medium sized, pure white, firm, compact heads, grown in thirteen weeks from time of sowing the seed. Mr. Ward sent a nice collection of Peas, receiving a cultural award, the varieties being Daisy, Stratagem, Carter's Favourite, and Telephone. Messrs. Mortimer and Thomas sent new Cucumbers, which the committee desired to be sent to Chiswick for trial next year. Messrs. Carter, High Holborn, sent two varieties of Spinach, the new Carter's, given an award last meeting, and the Long-standing, an older form, to show the difference in the two varieties. Mr. G. W. Cummins sent Runner Bean Ne Plus Ultra grown in pots. The new Excelsior Tomato, given an award last meeting, was again shown by Mr. Corbett, Mulgrave Castle Gardens, Whitby. Mr. R. Filkin, Christchurch, sent Potato Queen of the Earlies, Early Laxton and Maggie being sent for comparison. The Queen is very early, and has a good tuber, but no award was given, as the best test is a trial at Chiswick.

The lecture was by Professor Henslow, who kindly undertook to fill the vacancy caused by the unavoidable absence of Mr. W. T. Thistleton-Dyer. He greatly interested a numerous audience with interesting facts and peculiarities concerning many of the plants and flowers exhibited that day. He alluded to the great Cactus family as an instance of plants adapting themselves to their environment, for although the family contained many species of wide botanical differences, there was a wonderful similarity of aspect about them as a whole, and necessary, because either by their tough skin, or armour of spines, or mantle of hairs, they prevented the evaporation of their own juices and were able to subsist in the aridity of their surroundings. Even representatives of the Spurge family took the same succulent habit of growth in desert regions, and in outward aspect looked a different race of plants to the Spurges of our own woods. He showed coloured illustrations of the earliest types of the tuberous Begonia and compared them with the latest varieties shown that day, remarking incidentally that no future controversy could ever arise such as has been going on regarding the origin of the florist's Cineraria, as we knew the early types, and all the work that had been done with them was chronicled. The present type of Gloxinia that found most favour in gardens was that with a regular erect flower, which again was of garden origin, but represented, he thought, the reappearance of some latent trait, as botanically what we know as the wild type with a drooping flower had only four stamens, and was an irregular flower which cultivation had restored to regularity. Many other flowers he discoursed upon in the same pleasant and instructive way. More lectures of this sort might with advantage be given, alternating with those confined to one specific subject, if we may judge by the cordial way in which this one was received.

The Nurserymen, Market Gardeners' and General Haulstorm Insurance Corporation, Limited.—The statutory general meeting of this corporation was held at Simpson's, Limited, Strand, on Friday, June 21, 1895. The chairman (Mr. Harry J. Veitch) reported that the shares had been applied for freely, thus providing perfect security for policy-holders. Though established only four months, 100 policies had been issued on 6,720,832 square feet of glass, valued at £80,542 2s. 6d., and producing £415 11s. 6d. in

premiums. This amount would be considerably augmented by the Midsummer and Michaelmas business. No claims had yet been received. The capital had been invested in Government stock; twenty-six agents had already been appointed in the United Kingdom. The corporation was being worked with economy and was making good progress. The directors would take no remuneration in any year when less than 5 per cent. on the subscribed capital was made, and then only such sum as the shareholders in general meeting voted to them. From the tone of the meeting the report was considered very satisfactory. Messrs. Harry J. Veitch, James Sweet and James Webber were appointed trustees, and the meeting closed with a unanimous vote of thanks to the chairman.

## NOTES OF THE WEEK.

*Anemone rivularis* is a fine summer Anemone to which all who have a little bog or a moist nook in the rock garden should give a place. At Kew it is flowering strongly and well in quite an elevated position, its stout flower-stems nearly 2 feet in height, freely branched, and bearing many white flowers.

*Mertensia virginica*.—On page 447 "M. P." calls attention to the above plant. At the present time *M. virginica* is quite dormant, while a few yards away *Mertensia sibirica* and *M. paniculata* are in bloom. I should certainly say that the plant mentioned in THE GARDEN June 8 and 15 must be either *M. sibirica* or *M. paniculata*.—W. H.

*Wahlenbergia graminifolia* is found to be one of the easiest of this little race of Bell-flowers to grow at Kew, and it is now flowering there. The plant has a centre tuft of narrow grassy leaves and prostrate flower-stems which radiate from the centre, each terminated by a dense head of purple-blue flowers clustered like those of *Campanula glomerata*.

*Escallonia Phillipiana* has withstood the past winter in the open at Kew. It is one of the hardiest species, much hardier than those commonly planted, namely, *E. macrantha* and *E. rubra*. It makes a pretty mass or group on the turf, throwing out its shoots in a pretty arching way, clothing them in an abundance of small deep green leaves, and now the shoots are wreaths of tiny white blossoms like sprays of tiny Daisies.

*Moltkia petraea* is a pretty dwarf shrub now in flower in the rock garden at Kew. In growth and leafage it so much resembles Lavender, that one might take it for such when not in flower. Now, however, it is most distinct from Lavender and everything else, the little bushes covered with flower-spikes. The flowers, disposed in dense short spikes on stems about 6 inches long, are of a deep blue colour with exerted stamens of a reddish hue.

An abnormal Foxglove.—I am sending you by post a Foxglove which has such a curious blossom, that I think you may possibly like to see it. I have had two, if not three, other Foxgloves with similar blossoms at the top of the spikes, but none nearly so large as this one, which is 3½ inches in diameter. I raised these Foxgloves from seeds. The great majority have come up with the ordinary blossoms only.—LEONORA SCOTT, Malabar House, St. Albans.

*Brassia verrucosa*.—I send you a raceme of *Brassia verrucosa* cut from a plant bearing eighteen similar racemes with fifteen to sixteen blooms on a raceme. I also send you a couple of blooms of *Cypripedium barbatum* from a plant bearing forty blooms. I also enclose two blooms of a *Cypripedium* with a nice whitish dorsal sepal. The plant is bearing thirty-six blooms, and makes a handsome specimen.—J. F. WILKINSON, Highlands, Amberley.

*Solanum Wendlandi*.—A climbing plant that will succeed under the arid conditions essential for the growth of Cacti must surely be useful

in many gardens. Certainly none could fail to admire this magnificent plant as now flowering in the Cactus house at Kew, where it is trained to the roof, and produces an amazing profusion of richly coloured blooms. A coloured plate of this plant was given in THE GARDEN of Feb. 1, 1890, p. 104.

*Eremostachys laciniata* is a vigorous perennial belonging to the Sage family, but looking like a cut leaved *Acanthus* with its robust erect spike, of which the upper half is crowded with flowers. The flowers are of a greenish colour streaked with pale purple, but the conspicuous part of them is the lower petal or lip, which is of a rich dark velvet-crimson hue. It would be well worth while growing it in shade to preserve its colour till it faded naturally.

*Epilobium obcordatum*.—This is a native of the Rocky Mountains and a pretty plant for the rock garden, dwarfed doubtless because it was essential to do so to adapt itself to its natural environment, but preserving at the same time all its beauty of blossoms. It has a low spreading habit of growth, the shoots clothed with short broad leaves and the large flowers of a bright rosy crimson colour, each petal deeply cut into two lobes. It is flowering at Kew.

*Genista virgata*.—This pretty Broom is rarely seen outside of botanic gardens. At Kew it is now flowering freely, and established plants appear to have suffered little from the past winter. A mass of it has a lovely effect that is visible from a considerable distance, as the older specimens in the group are more than 12 feet high and have thick tree-like stems. The flowers in size and rich colour resemble those of *Cytisus racemosus*, but the racemes are shorter and borne freely.

*Syringa japonica* now flowering at Kew is a very graceful species, and if it will only flower as freely as other Lilacs it will be a most valuable sort for succession, as it is even now only opening some of its flowers, whilst those of all other kinds have long faded. The flowers are tiny individually, cream-white, with exerted yellow stamens that give a peculiar charm to the plant, but what they lack in size they make up in numbers, being thickly disposed in large, much-branched racemes that hang lightly upon the bush.

*Rosa Bruceana*.—Anyone searching for a beautiful single Rose that would climb a tree or quickly cover any crevice about the garden would not long be undecided if he saw the great plant of this Rose near the succulent house at Kew. Its main stem, trained to or grown up with other things, must be nearly 20 feet high, and it throws out in all directions long, arching shoots, having soft grey-green leaves and myriads of flowers in thick clusters. Their effect in the bright sun, the air laden with their fragrance, is something to remember, but by no means possible to describe.

*Rhododendron cinnabarinum*.—We have some fine plants of *Rhododendron cinnabarinum* in flower, and I thought you might like a few blooms from a plant about 16 feet or 17 feet high with some hundreds of flowers on it.—R. G. LAKES, Travarrick, St. Austell.

\* \* This *Rhododendron* was figured in THE GARDEN of March, 1879. It also does well in the neighbourhood of Dorking, and many fine plants exist in the west of England, but we think it is hardly suitable for general cultivation, as it undoubtedly wants a warm and sheltered situation. In such a place, however, it is well worthy of a trial by those who are fond of this class of plants.—ED.

Water Lilies at Kew.—One of the most interesting houses at Kew is that devoted to Water Lilies and other aquatic plants. At the present time there is a fine display of colour from many flowers of *N. Lotus* and *N. stellata*, in white, crimson and deep blue shades. We saw *N. Marlacea carnea* and *N. Leydekeri* flowering in the same tank, but scarcely happy there, the former not nearly so large as with us in the open air; and

N. Leydekeri seemed to lack that glow of bright colour which in the open water makes it so visible and brightly effective, even seen from a considerable distance. There are now so many noble hardy kinds that they ought to be represented at Kew growing in some open water where, without the least doubt, they would have thousands of admirers who as yet know them not in their newer and richly-coloured forms.

**Vegetables at York show.**—Some grand vegetables were shown at York on the 17th in competition for the prizes offered by Messrs. Webb and Sutton and Sons. In Mr. Crawford's collections, which won the first prize in both classes, that fine old Pea Stratagem was seen in grand form, it being of a much deeper green colour than the larger pods of Sutton's A 1 shown by Mr. McIndoe. The good old Watcheren Cauliflower was well represented, as were also Canadian Wonder Bean, Leviathan Onion, Market Favourite Carrot, the last being of large size for the time of year and of a bright colour. Sensation and Reading Perfection Tomatoes were also conspicuous in the various exhibits, and a fine bundle of late Argenteuil Asparagus gave great strength to one of Mr. Crawford's collections.

**Notes from Chester.**—It is Midsummer day. It looks it and feels like it without reference to the calendar. If at the early part of the spring-time there were grounds for the assertion that the season was late, Flora, impressed with the fact, seemed to quicken her pace, and everything is brought up to line by the time we have reached the longest day. The flowers and leafage everywhere are abundant and beautiful. It is not the sense of sight alone that is gratified. Amongst the Philadelphus bushes to day the perfumery of Nature forces itself upon the attention. In witness whereof place the two sprays beside you as you take them from the box of specimens just posted to you. *Philadelphus hybridus Lemoinei* is, as you will see, a beautiful variety of the Moek Orange, whilst *Philadelphus microphyllus* is as dainty a piece of graceful combination as you could wish to see. Then the *Clerodendron*, with its creamy Lychnis-like flowers, its inflated calyx like a piece of carved coral, and its long graceful stamens. What more delightful aroma could be found? For form, too, the *Zenobias*, seem to combine the characters of the *Erica* with all that is daintily beautiful in the chaste bells of the *Lily of the Valley*: are not these each charming in their way? We send you *Z. pulverulenta* and *Z. cassiniifolia*. There are some lovely *Deutzias* out now. The *Pride of Rochester*, a grand double-flowering variety, is enclosed, and may be taken as a representative of some other plants of this beautiful family flowering so freely. The *Clematises* are just coming to the front in their rich clusters about the pillars that

afford them the support they need. The beautiful form *integrifolia* var. *Davandi* we send to-day. Its rich purple is most effective against its healthy profusion of entire leaved foliage. *Escalonia Phillipiana* we also send a splendid piece of in pink and white with foliage suited to its floral arrangement.—DICKSONS.

## PUBLIC GARDENS.

**Plumstead Common fired.**—For the greater part of yesterday a fire was raging on Plumstead Common. The flames broke out about half-past ten in the morning, and spread with such rapidity, that in less than a couple of hours five acres of Furze and bushes were blazing. It was not until evening that the fire burnt itself out. This is the third fire which has occurred on the common during the present week.

**Brockwell Park.**—The Parks Committee recommended that £1470 should be expended in the construction and drainage of footpaths, the formation of two ornamental ponds, shrubberies, and a rivulet, the erection of rustic bridges and wire-fencing to the paths, and boundary fencing and gates at Arlingford Road. The land upon which this new entrance is to be erected will shortly be in possession of the council, and the work will be commenced without delay. Opposition to the scheme came from Dr. Longstaff, Mr. John Burns, and one or two other members, the ground of objection being that the cost was excessive. As chairman of the Parks Committee Mr. Fletcher showed that this was not the case, the proposed expenditure being quite within the scale of previous undertakings of the same kind. The council adopted the Parks Committee's recommendation by a substantial majority.

**The weather in West Herts.**—During the present month there have been as yet only five days in which the highest temperature in shade has been below the mean for the time of year, but, on the other hand, most of the nights have been more or less cold for the season. The three hottest days were the 9th, 23rd and 25th, when the readings in shade rose respectively to 80°, 80° and 79°. At the depth of 1 foot the soil temperature stands at 68°, which is 7° in advance of the June average, and 5° warmer than at the same date last year. The total fall of rain for the last six weeks amounts only to about a quarter of an inch; whereas a seasonable fall for the same period would exceed 3 inches. The ground is exceedingly dry; in fact, not a drop of water has come through the heavy soil gauge for a month or through the light soil gauge for six weeks. The air also still continues remarkably dry. On the 20th the difference at 3

p.m. between the dry and wet bulb readings amounted to 17°, and on the 25th to 20°. The well-known Hybrid Perpetual Rose Marie Baumann first flowered on the 24th, or, with the exception of 1893, earlier than in any of the seven previous years.—E. M., *Berkhamsted*.

## COLLECTING HARDY PLANTS.

TO THE EDITOR OF THE GARDEN.

SIR,—I write to know if there are other amateurs, caring for herbaceous and alpine plants, who would like to join and send out a collector to some of the still unexplored parts of the world. Nurserymen cannot afford to do this except in the case of Orchids and similar high-priced greenhouse things. But if fifty of us were to subscribe £10 each we could probably do anything we wanted in the Southern Andes, Alaska, or anywhere else we chose. Of course it would not pay from a business point of view, but it would give us a world of interest and pleasure raising the new seeds and bulbs, and would almost certainly give us a few things which would permanently enrich English gardens. I write in great ignorance of this matter. It may be the expenses would be much more than I think. It would be very interesting to hear what those who know about such enterprises can tell us. Anyhow, I would gladly risk £10 myself. And if it turns out that there are others similarly minded, we might arrange for a meeting in London and see if we can knock the idea into feasible shape.

ARTHUR K. BULLEY.

*West Kirby, near Birkenhead.*

## WINTER AND SPRING PICTURES.

AWARD OF PRIZES.

First prize, 10 guineas, is awarded to Miss Willmott, Warley Place, Great Warley, Essex, for over 200 good photographs of beautiful gardens and plants.

Second prize, 5 guineas, to the Countess of Annesley, Castlewellan, Co. Down, Ireland.

Equal third prize, 3 guineas, to Mr. S. W. Fitzherbert, Lanscombe House, Torquay, and Mr. J. C. Smith, Nandana, Penrith.

EXTRA PRIZES.

Miss Gaisford, Offington, Worthing. *Xanthoceras sorbifolia*, group of Snowdrops, *Prinos glaber*.

Mr. E. H. Woodall, St. Nicholas House, Scarborough. *Narcissus princeps*, *Galanthus plicatus*, *Scilla campanulata*.

Mr. Thomas Allott, 110, Shaw Heath, Stockport. Two views of Tulips in Ashton Park.

Mr. C. Metcalf, Mill House, Halifax. *Rhododendron* Lady Alice Fitzwilliam, *Arabis montana*.  
Rev. D. J. Gerrard, The Rectory, Rathangan, Co. Kildare. Apple tree in bloom.
